# Predator Prey Example

Jessica Burnett and Nathaniel Price 2019-01-29

### 1 Two-Species Model System

This example is based on the system described in Exploratory Data Analysis Using Fisher Information (Mayer et al. 2007; Frieden and Gatenby 2007, 229–31). The two species Lotka-Volterra differential equations for the system are

$$\frac{dx_1}{dt} = g_1 x_1 \left( 1 - \frac{x_1}{k} \right) - \frac{l_{12} x_1 x_2}{1 + \beta x_1}$$
$$\frac{dx_2}{dt} = \frac{g_{21} x_1 x_2}{1 + \beta x_1} - m_2 x_2$$

The model parameters are  $g_1 = m_2 = 1$ ,  $l_{12} = g_{12} = 0.01$ , k = 625, and  $\beta = 0.005$ . The initial conditions for the system were not provided in the original reference (Mayer et al. 2007). We found that  $x_1 = 277.7815$  and  $x_2 = 174.551$  provide reasonable results. The differential equations for the system are defined in R as shown below.

```
# Model parameters
parameters <- c(
  g1 = 1,
  m2 = 1,
  112 = 0.01,
  g21 = 0.01,
  k = 625
  B = 0.005
# Initial conditions
state <- c(
  x1 = 277.7815,
  x2 = 174.551
# System differential equations (eq. 7.17 and 7.18)
deq <- function(t, state, parameters) {</pre>
  with(as.list(c(state, parameters)), {
    dx1dt \leftarrow g1 * x1 * (1 - (x1 / k)) - (112 * x1 * x2) / (1 + B * x1)
    dx2dt \leftarrow (g21 * x1 * x2) / (1 + B * x1) - m2 * x2
    list(c(dx1dt, dx2dt))
  })
}
```

We use the package deSolve to solve the system of differential equations. The original reference did not provide the time the system was observed (Mayer et al. 2007). We found that a complete cycle of the system corresponds to approximately 11.145 time units. The system of differential equations is solved and the system trajectory is plotted below.

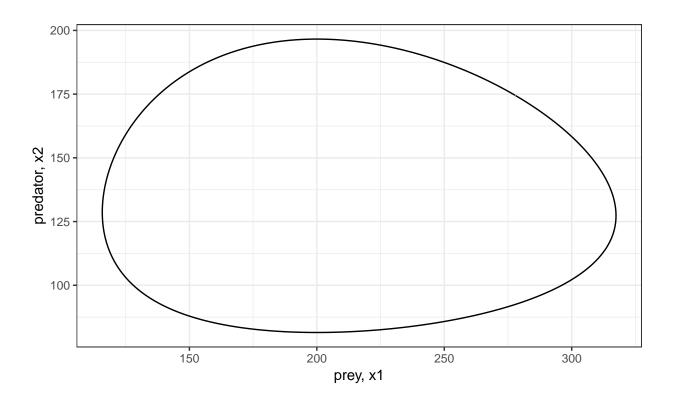

Figure 1: Phase space plot of system

```
# Vector of times
TT <- 11.145
times <- seq(0, TT, by = TT/1e3)
\# Solve system differential equations
out <- ode(</pre>
  y = state,
  times
  = times,
 func = deq,
 parms = parameters,
 rtol = 1e-10,
  method = "ode45"
)
# Convert to data frame
sysSol \leftarrow data_frame(t = out[,1], x1 = out[,2], x2 = out[,3])
## Warning: `data_frame()` is deprecated, use `tibble()`.
## This warning is displayed once per session.
```

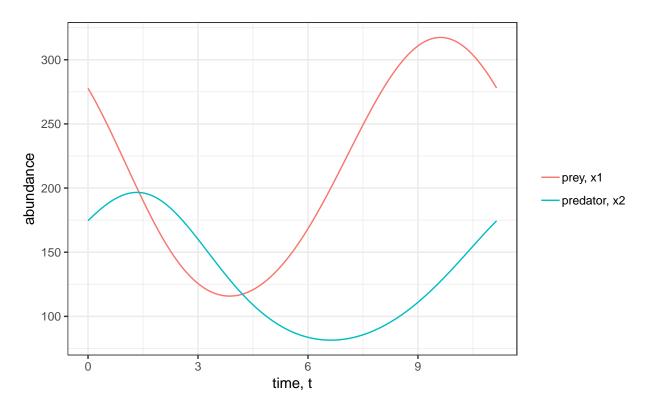

Figure 2: Change in predator and prey abundance over time

# 2 System State PDF & Dimensionality Reduction

The state of the system at any point in time, t, is defined in two dimensions by the number of prey,  $x_1$ , and the number of predators  $x_2$ . Let  $\mathbf{x} = [x_1, x_2]$  represent the state of the system. The probability of observing the system in a particular state can be approximated based on a 2-dimensional histogram as shown below. Note that the system does not change at a constant rate (i.e., does not travel the path at a constant speed) and is therefore more likely to be observed in some states than others.

```
# Initial conditions including distance
state_high0 <- c(</pre>
  x1 = 277.7815,
  x2 = 174.551,
  dx1dt = -48.6,
  dx2dt = 28.3,
  d2x1dt2 = -23.3,
  d2x2dt2 = -10.5,
)
# Model parameters
parameters_high0 <- c(</pre>
  g1 = 1,
  m2 = 1,
  112 = 0.01,
  g21 = 0.01,
  k = 625,
```

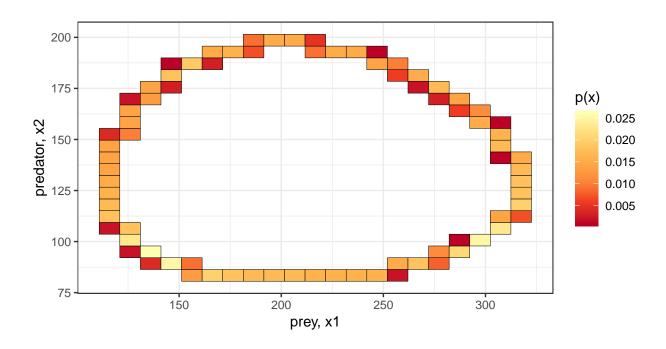

Figure 3: Normalized histogram showing probability of observing particular system states

```
B = 0.005
# System differential equations including higher order terms and distance
deq_high0 <- function(t, state, parameters) {</pre>
                with(as.list(c(state, parameters)), {

```

#### 3 Fisher Information

The pdf of distance, p(s), was derived above. There are several equivalent equations for calculating shift-invariant FI. Some may offer numerical advantages over others. The general form is (Mayer et al. 2007, eq. 7.3b)

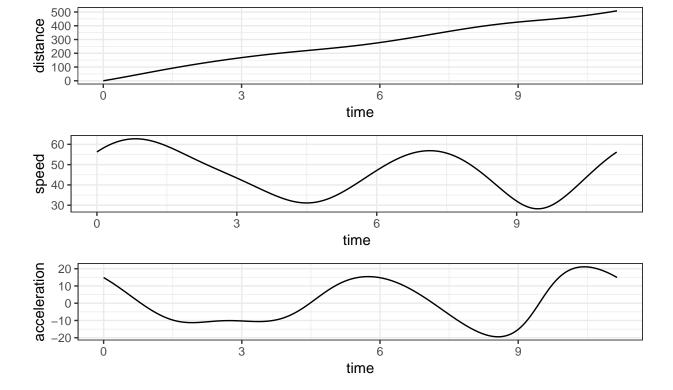

Figure 4: From top to bottom, distance traveled in phase space, speed tangential to system trajectory, acceleration tangential to system trajectory.

$$I = \int \frac{ds}{p(s)} \left[ \frac{dp(s)}{ds} \right]^2$$

The amplitude form is (Mayer et al. 2007, eq. 7.3c)

$$I = 4 \int ds \left[ \frac{dq(s)}{ds} \right]^2$$

A form specific to the pdf of distance traveled is derived as (Mayer et al. 2007, eq. 7.12)

$$I = \frac{1}{T} \int_0^T dt \left[ \frac{s''^2}{s'^4} \right]^2$$

where integration is performed in the time domain. While all these formulations are equivalent, the last is most readily calculated when the differential equations for the system are known. Below all equations are shown to be equivalent. The FI for the distribution of distance is calculated to be approximately  $5.4 \times 10^{-5}$  which is consistent with published results (Mayer et al. 2007, 232).

```
# Equation 7.3b

## 4 Varying carrying capacity for the prey

Here we replicate the results of varying the prey carrying capacity, k (Mayer et al. 2007).

## 5 Regime shift - Habitat destruction

Simulate a regime shift by abruptly decreasing the carrying capacity for the prey. The change in carrying capacity for the prey over time was modeled as

$$k(t) = k_1 - 0.5(k_1 - k_2)(\tanh(\alpha(t - t^*)) + 1)$$

where  $k_1$  is the initial carrying capacity,  $k_2$  is the final carrying capacity,  $t^*$  is the time of the regime shift, and  $\alpha$  is a parameter that controls how abruptly the carrying capacity changes. The rate of change of the carrying capacity is given by

$$k'(t) = 0.5\alpha(k_1 - k_2)(\tanh(\alpha(t - t^*))^2 - 1)$$

```
# Time of regime shift
tregime = 200

# Carrying capacity for regime 1 and regime 2
k1 <- 800</pre>
```
