¹⁷⁹ Abstract

¹⁸⁰ Identifying abrupt changes in the structure and functioning of systems, or system
¹⁸¹ regime shifts, in ecological and social-ecological systems leads to an understanding
¹⁸² of relative and absolute system resilience. Resilience is an emergent phenomenon of
¹⁸³ complex social-ecological systems, and is the ability of a system to absorb disturbance
¹⁸⁴ without reorganizing into a new state, or regime. Resilience science provides a
¹⁸⁵ framework and methodology for quantitatively assessing the capacity of a system to
¹⁸⁶ maintain its current trajectory (or to stay within a certain, and often desirable regime).
¹⁸⁷ If and when a system's resilience is exceeded, it crosses a threshold and enters into an
¹⁸⁸ alternate regime (or undergoes a regime shift).

¹⁸⁹ I will use Fisher Information to detect regime shifts in time and space using avian
¹⁹⁰ community data obtained from the North American Breeding Bird Survey within the
¹⁹¹ area east of the Rockies and west of the Mississippi River. Fisher Information is a
¹⁹² technique that captures the dynamic of a system, and this metric will be calculated
¹⁹³ about a suite of bird species abundances aggregated to the route level for all possible
¹⁹⁴ time periods. Transmutation (aggregation error) about inclusion or exclusion of
¹⁹⁵ certain bird species, functional groups, and guilds will be analyzed. Efforts have been
¹⁹⁶ made to develop early warning indicators of regime shifts in ecosystems, however, for
¹⁹⁷ most ecosystems there is great uncertainty in predicting the risk of a regime shift,
¹⁹⁸ regarding both when and how long it will take to happen and if it can be recognized
¹⁹⁹ early enough to be avoided when desired. We will complement the use of Fisher

200 Information with multiple discontinuity analyses about body mass distributions at
201 the route-level to achieve the aim of identifying individual species that best serve
202 as early-warning indicators of regime shifts. For those species found on the edges
203 of body mass aggregations, we test the hypothesis that the background variance in
204 their abundances (on Breeding Bird Survey routes) will increase more than those not
205 observed at the edge of discontinuity aggregations. Identification of early-warning
206 indicators of regime shifts in ecological systems allows management efforts to focus on
207 a single or a small number of species that inform us about ecosystem resilience and
208 trajectory.

209 These methods transcend the primary objective of the Breeding Bird Survey (to monitor
210 population trends) and use this expansive dataset in such a way that information
211 about ecosystem order, trajectory, and resilience emerge. Here, we utilize an expansive
212 dataset (the Breeding Bird Survey) to make broad-scale estimations and predictions
213 about ecosystem resilience, regime status and trajectory, and ecosystem sustainability.
214 Identification of regime shifts and early-warning indicator species may afford us the
215 ability to predict system regime shifts in time.

²¹⁶ Table of Definitions

²¹⁷ Research surrounding regime shifts, threshold identification, change-point detection,
²¹⁸ bifurcation theory, etc. is muddled with jargon. Here, I provide a table of definitions
²¹⁹ (Table 1) for terms and concepts that may either be unfamiliar to the practical
²²⁰ ecologist, or may have multiple meanings among and within ecological researchers and
²²¹ practitioners. With this table, I aim to both improve the clarity of this dissertation
²²² *and* highlight one potential issue associated with regime detection methods in ecology:
²²³ semantics.

Table 1: A table of definitions for terms, theories, and phrases often appearing in ecological regime shift literature.

Term	Definition	Synonyms
Abrupt	A relative value of the speed and/or intensity of the change; the time period over which the regime shift occurs relative to the time observed (or expected to have been) in a particular state.	big, fast, quick, large
Alternative	Controversially can be distilled as one of either:	
Stable State	the number of unique stable configurations that a system can adopt (see Lewontin 1969), or the impacts that processes or pressures can have on a system's state (see May 1977).	
Attractor	The set of values towards which a system tends regardless of its initial (starting) vaules.	

Table 1: A table of definitions for terms, theories, and phrases often appearing in ecological regime shift literature. (*continued*)

Term	Definition	Synonyms
Basin-Boundary	The parameter values for a system that causes the system to shift between alternate attractors.	non-local bifurcation
Collision		
Catastrophe Theory	The study of abrupt changes within a dynamical system.	
Catastrophic Bifurcation	A relatively abrupt jump to an alternate attractor due to initial attractor.	
Change-Point	See also 'Regime Shift'. A term often used in computer science, climatology, data science; represents the point at which a state changes its configuration.	
Change-Point Detection	A change point method which does not require supervision; identifies potential change points without a priori potential change points.	
Change-Point Estimation	A change point method which DOES require supervision; identifies potential change points when given a set of potential change points; well-developed in computer science, statistics, data mining, etc.; although well-developed, still lacks with giving statistical significance of change-points.	
Chaos	A system with extreme sensitivity to initial conditions.	
Critical Slowing Down (CSD)	When the recovery rate (time to return) of a system decreases (approaches zero) as a system approaches a critical point (possibly a threshold or tipping point). A characteristic observed in some empirical systems data (e.g. nutrient loading in shallow lakes).	
Degrees of Freedom	The number of system parameters or components which vary independently.	

Table 1: A table of definitions for terms, theories, and phrases often appearing in ecological regime shift literature. (*continued*)

Term	Definition	Synonyms
Domain of Attraction	The range of values around which a system fluctuates.	zone of fluctuation, basin of attraction, stable point, attractor
Driver	A widespread anthropogenic source of change which leads to one or more pressures (e.g., land-use change).	
Driver-Threshold	When a rapid change in external driver induces a rapid	
Regime Shift	change in ecosystem state.	
Dynamical System	A time-dependent system which can be described in state-space.	
Dynamical Systems Theory	The study of complex systems theory; the study of time-dependent systems.	
Equilibrium	The set of values around which a system revolves and does not change.	
Exogeneous Process (Forcing, Driver)	An external process influencing the state of the dynamical system.	
First-Order Stationarity	When the mean is constant over the observations.	
Fold Bifurcation	This occurs when a stable point collides with an unstable point; when crossing a tipping point induces hysteresis.	
Fractal Properties	A measurement of geometrical self-similarity; when a system has similar structure regardless of the scale of observation.	ergodic

Table 1: A table of definitions for terms, theories, and phrases often appearing in ecological regime shift literature. (*continued*)

Term	Definition	Synonyms
Hysteresis	A system which is state-dependent (e.g. magnets); when a tipping point or threshold is crossed such that the previous state cannot be achieved by reversing the conditions.	
Leading Indicators	When the statistical properties of the fluctuations (of the data) approach a critical transition.	
Lyapunov Exponent (and Stability)	A value that conveys the average rate of trajectory divergence that is caused by an endogenous force; how quickly (if at all) a system will tend away from a stable point if it starts near the stable point.	
Measure Theory	The study of measures and measurement (e.g. volume, mass, time).	
Moving (Sliding) Window Analysis	When a subsample of the data $\$X_t\$$ is used in lieu of a single observation, $\$x_t\$$.	
Noise	Processes manifested in data which are unaccounted for; sometimes referred to as meaningless; random variability.	
Non-Stationarity of the Mean Value	Infers that a trend or a periodicity is present in the time series.	
Online	Real-time updating of model parameters, predictions, etc. (c.f. offline).	
Persistent	A relative value of the longevity of the observed change in values.	long-lasting
Phase Space	A graphical representation of two or more trajectories where one axis is not time. In this representation an equilibrium is defined as a single point in the state space.	

Table 1: A table of definitions for terms, theories, and phrases often appearing in ecological regime shift literature. (*continued*)

Term	Definition	Synonyms
Prediction	A temporal forecast. Is intrinsic when a model and parameters are used to make forecast, is realized when the prediction becomes the actual state of the system.	
Pressure	A perturbation which negatively influences a system, and can be defined as pulse, press, or monotonic.	
Red Noise	Noise having zero mean, constant variance, and serial autocorrelation; autocorrelated random variability.	
Regime	A set of system values that define a particular system state. Not necessarily stable, but some state variables or outputs of the system remain relatively constant over a defined period of time.	
Regime Shift	"abrupt" and "persistent" change in a system's structure or functioning.	
Second-Order	The mean is constant and the covariance is a function of a time lag, but not of time.	
Stationarity		
Self-Similarity	A system satisfied by power-law scaling.	
Stable	An equilibrium is stable when small perturbations do not induce change.	
Equilibrium		
State Space	The set of all possible configurations of a system.	
State-		
Threshold	When a gradual change in external driver induces a rapid change in ecosystem state (e.g., System crosses a threshold).	
Regime Shift		
Stationarity	When the probability density function of a system does not change with time.	

Table 1: A table of definitions for terms, theories, and phrases often appearing in ecological regime shift literature. (*continued*)

Term	Definition	Synonyms
Statistical	A system with statistical properties unchanging over time. This concept extends to periodic stationarity for systems exhibiting periodic behavior.	
Stationarity		
Strange Attractor	An attractor which has fractal structure (an observable fractal dimension).	
Supervised	When classifiers are used to train the data a priori.	
Machine Learning		
System State	The observed (current) instance of the system within a state space.	
Threshold	A point where the system reacts to changing conditions.	
Tipping Point	A point in a system's trajectory where a small change in an endogenous force induces a large change in system state or values; the point where a system can flip into an alternative state.	
Trajectory	The path of an object or system through space-time.	orbit, path
Transient	A behavior or phenomenon which is responsive to initial (starting) conditions, or its effect declines over time.	
Trend	Local averaging of values such that the non-systematic components of the system are washed out.	
Smoothing		
Unstable	An equilibrium is unstable when small perturbations induce change.	
Equilibrium		

Table 1: A table of definitions for terms, theories, and phrases often appearing in ecological regime shift literature. (*continued*)

Term	Definition	Synonyms
Unsupervised	When no prior training of the data is required	
Machine Learning	(i.e. no classifications necessary <i>a priori</i>) to classify it.	
White Noise	Noise having zero mean, constant variance, and is not autocorrelated; uncorrelated random variability.	

²²⁴ Chapter 1

²²⁵ Introduction

²²⁶ Anthropogenic activity in the last few decades will continue to influence the interactions
²²⁷ within and among ecological systems worldwide. The complexity of and drivers of
²²⁸ changes in coupled human-natural systems is consequently altered, further limiting our
²²⁹ ability to detect and predict change and impacts of change (Liu et al., 2007; Scheffer,
²³⁰ 2009). Early warning systems are developed to detect, and in some cases predict,
²³¹ abrupt changes in disparate systems [e.g. cyber security [@!!!!], infrastructure [@!!!!],
²³² banking crises (Davis & Karim, 2008), and agricultural systems]. The need to develop
²³³ and improve early warning systems for natural and coupled human-natural systems is
²³⁴ exacerbated by the consequences of climate change and globalization, especially when
²³⁵ the human-related stakes are high.

²³⁶ 1.1 Forecasting abrupt changes in ecology

²³⁷ Forecasting undesirable change is, arguably, the holy grail of ecology. Paired with
²³⁸ an understanding of system interactions, a forecast is ideal if it provides reliable
²³⁹ forecasts with sufficient time to prevent or mitigate unwanted systemic change. Early
²⁴⁰ warning systems (or early warning signals, or early warning indicators) have been
²⁴¹ developed and tested for some ecological systems data (especially marine fisheries time

series and for nutrient loading in shallow lakes). Despite the quantitative methods proposed as early warning systems for ecological data (hereafter referred to as regime detection measures, RDMs), many are currently of limited practical utility. This paradox may be a consequence of existing ecological early warning systems (or other quantitative methods for identifying systemic change) having one or more of the following characteristics:

1. not generalizable across systems or system types (especially when it requires a model or a deterministic function to describe the system)
2. require a large number of observations
3. difficult to implement
4. difficult or to interpret
5. requires an understanding of the drivers of change
6. performs poorly under uncertainty
7. give no uncertainty around estimates (tying into interpretation issues)
8. cannot handle noisy data
9. ignores or does not sufficiently account for observation error
10. no baseline with which to compare results
11. no application/testing on empirical systems data
12. systems are subjectively bounded (i.e., components are chosen)
13. being overshadowed by semantics
14. are based on two observations (e.g., before-and-after)
15. cannot link the shift to potential drivers (i.e. the method reduces the dimensionality such that it is unitless and/or loses all relevant information)

Research focusing on the above areas as they relate to RDMs will contribute to the advancement and improvement of existing early warning systems, and will, hopefully, highlight methods which are useful and which are not to practitioners and decision makers.

269 1.2 Dissertation aims

270 The overarching aim of this dissertation is to advance our understanding of the utility
271 and limitations of select early warning systems. Specifically, I focus on RDMs capable
272 of analyzing multi-variable data, including temporally- and spatially-explicit. Although
273 the most widely-applied RDMs proposed in the ecological literature are those developed
274 for and tested on single-variable time series (e.g., temperature or fisheries stock time
275 series), the utility of these methods in multi-variable systems (data) is limited. Regime
276 detection metrics for tracking and identifying changes in multivariable systems data are
277 of greater use than single-variable RDMs in systems within which a change manifests
278 dynamically and across multiple variables (e.g., species). Multivariable RDMs may
279 also prove advantageous when the drivers of systemic change are unknown. Further,
280 ecological systems are noisy, and ecological systems data are messy.

281 Although it's taken us many decades to produce reliable weather forecasts 5
282 days out (and climate is a low-number system..), ecologists produce regime detection
283 methods with the promise of predicting high-dimensional ecosystem change in advance.
284 Many of these RDMs are not models, like the weather forecasting models which have
285 taken years to refine.

286 1.3 Dissertation structure

287 1.3.1 Chapter overview

288 The dissertation comprises a brief introduction (Chapter 1), an overview of the myriad
289 regime detection measures used or proposed for use with ecological data (Chapter
290 2), a detailed guide to Fisher Information as a RDM written for the lay ecologist
291 (Chapter 3), an application of Fisher Information to spatially-explicit data (Chapter
292 4), introduction of a new regime detection measure, velocity (v) (Chapter 5), a study

293 of data quality and data loss on select regime detectiob measures (Chapter 6), an
294 application of body mass discontinuity analysis to spatially explicit data (Chapter 7),
295 and a synthesis and conclusions chapter (Chapter 2.6).

296 **1.3.2 Accompanying software (appendices)**

297 This dissertation is accompanied by the vignettes for two software I created, which
298 are publicly available for use (MIT use and distribution license). The first is
299 `regimeDetectionMeasures` (Appendix ??), is an R package for calculting multi-
300 ple regime detection measures, and the second, `bbsRDM` (Appendix ??), is a package
301 which downloads and uses the North American Breeding Bird Survey data to calculate
302 regime detection measures (using `regimeDetectionMeasures`).

³⁰³ **Chapter 2**

³⁰⁴ **A brief overview of ecological
305 regime detection methods methods**

³⁰⁶ **2.1 Introduction**

³⁰⁷ *If a regime shift occurs and no one detects it—is it a regime shift at all?*

³⁰⁸ **No**, if the regime shift is defined as a change in a system which negatively
³⁰⁹ impacts humans. **Yes** if the regime shift is defined simply as a shift in the
³¹⁰ underlying strucutre of a system.

³¹¹ Long-lasting changes in the underlying structure or functioning of natural systems
³¹² due to exogeneous forcings (also called regime shifts) is of interest to ecologists. The
³¹³ ability to identify and predict these shifts is particularly useful for systems which are
³¹⁴ actively managed, provide ecosystem services, or provide benefit to society. Despite
³¹⁵ the utility of identifying and refining the regime detection methods (or early warning
³¹⁶ signals or indicators), there exists a disparity among the number of methods proposed
³¹⁷ for detecting abrupt changes in ecological, oceanographic, and climatological systems
³¹⁸ and the studies evaluating these methods using empirical data (@ Hawkins, Bohn, &
³¹⁹ Doncaster, 2015). Further, new methods continue to permeate the literature despite

320 this disparity. Although reviews of regime shift detection methods exist (Andersen,
321 Carstensen, Hernández-García, & Duarte, 2009; Boettiger, Ross, & Hastings, 2013;
322 Clements & Ozgul, 2018; Dakos et al., 2015a, 2015b; deYoung et al., 2008; Filatova,
323 Polhill, & Ewijk, 2016; Kefi et al., 2014; Litzow & Hunsicker, 2016; Mac Nally, Albano,
324 & Fleishman, 2014; Mantua, 2004; Roberts et al., 2018; S. N. Rodionov, 2005; Scheffer,
325 Carpenter, Dakos, & Nes, 2015), the most comprehensive presentation of available
326 methods as they are outdated (S. N. Rodionov, 2005)*¹

327 Perhaps given the sheer number of methods available, there is not currently a single,
328 comprehensive source to which the practical ecologist can refer for identifying potential
329 regime detection measures. Prior reviews of this literature vary in both the number
330 and detail of the methods presented, often focusing on a single aspect of regime shift
331 theory (Andersen et al., 2009), or relaying methods to disciplinary audiences (Roberts
332 et al., 2018). Here I present a brief, systematic review of the methods proposed as
333 what I will call regime detection methods (RDMS) in the ecological literature. I also
334 synthesize the RDMs which are designed to identify ecological regime shifts under
335 uncertainty. I.e., when the regime shift is not hypothesized *a priori*.

336 Methods proposed for detecting ecological regime shifts (RDMs) are not easily
337 identified using systematic literature review techniques for several reasons. First, the
338 terminology associated with regime shift detection methodologies is highly variable
339 within and among fields (Andersen et al., 2009). For example, the terms, *regime shifts*,
340 *regime changes and tipping points* are variably used in studies of ecological systems,
341 whereas *inhomogeneities* is common in meteorology and climatology and *structural*
342 *change* is largely confined to econometrics. Although semantics vary both within
343 and across disciplines (e.g., a regime shift vs. a structural change), many methods
344 are shared or concurrently applicable. Second, papers introducing a new method or
345 approach to identifying regime shifts are not often proposed in publication outlets with

¹I also refer the reader to Kefi et al. (2014) and Yin, Leroux, & He (2017) spatial methods, and to Ducré-Robitaille, Vincent, & Boulet (2003) select tests for homogeneity in climate data.

³⁴⁶ aims of disseminating new quantitative methods (e.g., *Ecological Modelling*, *Methods*
³⁴⁷ in *Ecology and Evolution*). Rather, many new methods are published in journals with
³⁴⁸ refined (e.g., *Entropy*, *Progress in Oceanography*), as opposed to broader scope scopes
³⁴⁹ (e.g., *Ecology* and *Nature*).

³⁵⁰ Some RDMs require the use of mechanistic models however some methods fall
³⁵¹ into the category of model-independent (or model-free), or they require only simple
³⁵² autoregressive (AR) models. In most situations, the practical ecologist will have
³⁵³ insufficient data or a limited understanding of the system with which to parameterize
³⁵⁴ even the simplest mechanistic models. The regime detection measures requiring
³⁵⁵ only a limited or no understanding of the mechanisms generating the observed data,
³⁵⁶ I synthesize the utility of these methods here. Further, I synthesize methods not
³⁵⁷ requiring an *a priori* hypothesis about if and where the regime shift occurred.

³⁵⁸ 2.2 Methods

³⁵⁹ To identify the extent to which these methods are not obvious to the practical ecologist,
³⁶⁰ I conducted a systematic literature review. I attempted to identify original papers
³⁶¹ which introduce new, quantitative RDMs. Although the review method was to detect as
³⁶² many methodological papers as possible, most RDMs of which I was previously aware
³⁶³ were not identified using a systematic technique. Therefore, while highlighting the
³⁶⁴ literature search results, I also provide the missing methods. Finally, I synthesize the
³⁶⁵ methods which may be of most utility to the practical ecologist who wishes to identify,
³⁶⁶ rather than confirm, the presence of an ecological regime shift, placing emphasis on
³⁶⁷ methods which can handle multivariable datum coupled with a limited understanding
³⁶⁸ of system dynamics.

³⁶⁹ **2.2.1 Identifying candidate articles**

³⁷⁰ **1. Identifying regime detection methods**

³⁷¹ Candidate articles were identified for two reasons: 1) a bibliographic analysis of regime
³⁷² shift relevant papers in ecology and 2) to identify regime detection methods proposed
³⁷³ in the literature. The data used for the latter (identify methods) are a subset of the
³⁷⁴ data used for the former (bibliographic analysis).

³⁷⁵ I first queried the Thomson-ISI Web of Science (WoS) database (on 06 March
³⁷⁶ 2019) to identify articles which mention terms related to regime shifts, or abrupt
³⁷⁷ changes, using the following boolean: > TS=((“regime shift” OR “regime shifts” OR
³⁷⁸ “regime change” OR “regime changes” OR “catastrophic change” OR “catastrophic
³⁷⁹ shift” OR “catastrophic changes” OR “catastrophic shifts” OR “sudden change” OR
³⁸⁰ “sudden changes” OR “abrupt shift” OR “abrupt shifts” OR “abrupt change” OR
³⁸¹ “abrupt changes” OR bistab* OR threshol* OR hystere* OR “phase shift” OR “phase
³⁸² shifts” OR “phase change” OR “phase changes” OR “step change” OR “step changes”
³⁸³ OR “stepped change” OR “stepped changes” OR “tipping point” OR “tipping points”
³⁸⁴ OR “stable states” OR “stable state” OR “state change” OR “state changes” OR
³⁸⁵ “stark shift” OR “stark change” OR “stark shifts” OR “stark changes” “structural
³⁸⁶ change” OR “structural changes” OR “change-point” OR “change point” OR “change-
³⁸⁷ points” OR “change point” OR “break point” OR “break points” OR “observational
³⁸⁸ inhomogeneity” OR “observational inhomogeneities”) AND (“new method” OR “new
³⁸⁹ approach” OR “novel method” OR “novel approach”))

³⁹⁰ where ‘*’ indicates a wildcard.

³⁹¹ Limiting the search to the fields of ‘Ecology’ and ‘Biodiversity Conservation’
³⁹² (by including WC=(Ecology OR ‘Biodiversity Conservation’) to the above boolean)
³⁹³ excludes many methods used solely in climatology, physics, and data science/computer
³⁹⁴ science literatures, where change-point analyses are abundant. Although additional

395 methods could be identified by searching these fields, this dissertation focuses on using
396 methods for analysing *multivariable* data. Consequently, many methods for analysing
397 abrupt breaks in a single longitudinal data are excluded in this review.

398 To obtain a reasonable number of articles I further filtered the results to identify
399 articles which propose a ‘new’ method by retaining papers which included at least one
400 of the following phrases in the title and/or abstract: > ‘new method’, ‘novel method’,
401 ‘new approach’, ‘new practical method’, ‘new simple method’, ‘new multivariate’,
402 ‘new tool’, ‘novel tool’, ‘novel multivarte’, ‘novel approach’, ‘new numerical’, ‘novel
403 numerical’, ‘new quantitative’, ‘novel quantitative’, ‘i introduce’, ‘we introduce’

404 I removed articles from this query based on both prior knowledge (in my personal
405 database) and those highlighted in previous reviews related to regime detection
406 measures (Andersen et al., 2009; Boettiger et al., 2013; Clements & Ozgul, 2018;
407 Dakos et al., 2015a, 2015b; deYoung et al., 2008; Filatova et al., 2016; Kefi et al.,
408 2014; Litzow & Hunsicker, 2016; Mantua, 2004; Roberts et al., 2018; S. N. Rodionov,
409 2005; Scheffer et al., 2015).

410 There appeared disparity among the number of methods of which I was previously
411 aware and those identified in an initial Web of Science review. In an attempt to identify
412 as many new methods as possible I conducted an informal search of the Google Scholar
413 database, a database notoriously broader in scope than other academic dataabses.

414 The length of boolean for the Google Scholar database is limited by the number of
415 characters. Unfortunately, this, coupled with the wide breadth of Google Scholar’s
416 search boundaries, limits the capacity to which Google Scholar can be used to refine the
417 literature to a manageable number of articles. For these reasons I arbitrarily skimmed
418 the titles of the first 25 pages of the Google Scholar results (25 pages = 250 articles).

419 It should be noted that the order of terms appearing in the boolean are regarded as
420 the order of desired relevancy. I used the following boolean to identify these articles
421 in Google Scholar: > (‘regime shift’ OR ‘regime change’ OR ‘tipping point’) AND

422 ('new method' OR 'new approach' OR 'novel method' OR 'novel approach')

423 The candidate articles identified by Google Scholar and Web of Science contained
424 numerous articles proposing a new framework for identifying regime shifts rather than
425 new methods. As this chapter concerns the latter (new methods) I excluded these by
426 removing articles proposing a “new” combination of previously-used methods (see
427 Kong et al., 2017; Seddon, Froyd, Witkowski, & Willis, 2014; Vasilakopoulos, Raitsos,
428 Tzanatos, & Maravelias, 2017). I also did not consider papers which made relatively
429 minor adjustments or recommendations to existing methods (Zhou & Shumway, 2008;
430 but see K. Nicholls et al., 2011 for an addition of variable optimization to the method in
431 @nicholls_detection_2011 that was not included in the results) or articles proposing
432 new methodologies in mathematical journals (Byrski & Byrski, 2016; Salehpour,
433 Gustafsson, & Johansson, 2011) that have yet to be associated with or tested on
434 ecological data, or suggested to be useful for empirical data.

435 2. Bibliographic analysis of ecological regime shift literature

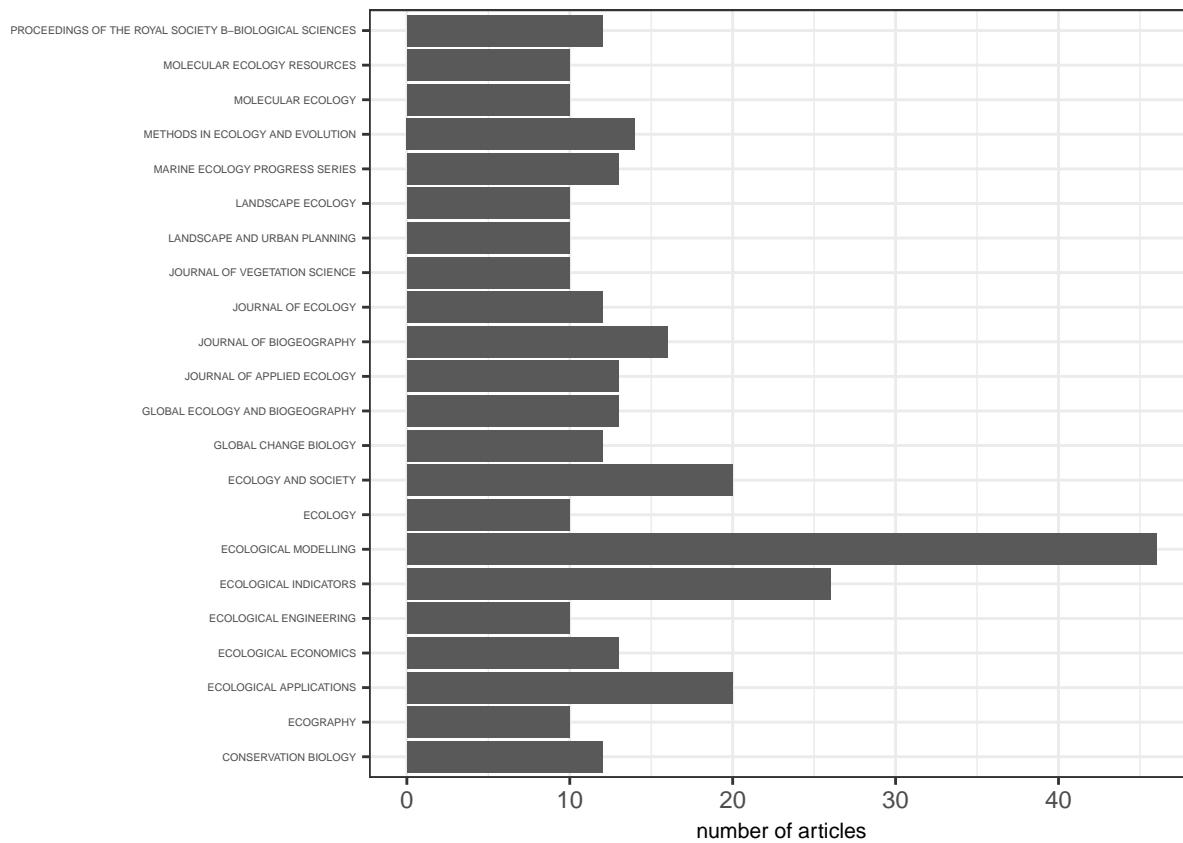

436 The still vague definition of ecological regime shifts has led to a breadth of articles
437 exploring systemic changes in nature. As such I conducted an exploratory bibliographic
438 analysis of the ecological regime shift literature. To achieve this, I identified candidate
439 articles in Web of Science using a boolean containing words relating to regime shift
440 and restricting the fields to Ecology and Biodiversity Conservation: > TS=(“regime
441 shift” OR “regime shifts” OR “regime change” OR “regime changes” OR “catastrophic
442 change” OR “catastrophic shift” OR “catastrophic changes” OR “catastrophic shifts”
443 OR “sudden change” OR “sudden changes” OR “abrupt shift” OR “abrupt shifts”
444 OR “abrupt change” OR “abrupt changes”) AND WC=(“Ecology” OR “Biodiversity
445 Conservation”)

446 I constructed a variety of networks based on co-citation and keyword co-occurrence
447 metrics to identify trends in the current state and development of the ecological regime

shift literature. I used the package R `bibliographix` (Aria & Cuccurullo, 2017) to construct the networks, whih uses various algorithms to statistically identify clusters. I focus results on keywords and concept themes, rather than citations and author dominance, in an attempt to undertand the evolution of regime shift methodologies in the ecological (and biodiversity conservation) literature.

2.3 Results

2.3.1 1. Literature review results

455

The search boolean for WoS boolean *not* including restriction to fields (WC) ‘Ecology’ and ‘Conservation Biology’ yielded over 20,000 results. Restricting to the above-mentioned fields created a manageable database from which to filter. This search yielded 2,776 articles. 654 of these papers included terms relating to ‘regime shifts’ (Figure 2.1), many appearing in the journal *Ecological Modelling* (Figure ??). The

⁴⁶¹ rate of publication of ‘regime shift’ articles is not strongly correlated with the rate
⁴⁶² of papers published in ‘Ecology’ and ‘Biodiversity Conservation’ fields (Figure 2.2).
 Filtering the Web of Science results by including only articles mentioning terms

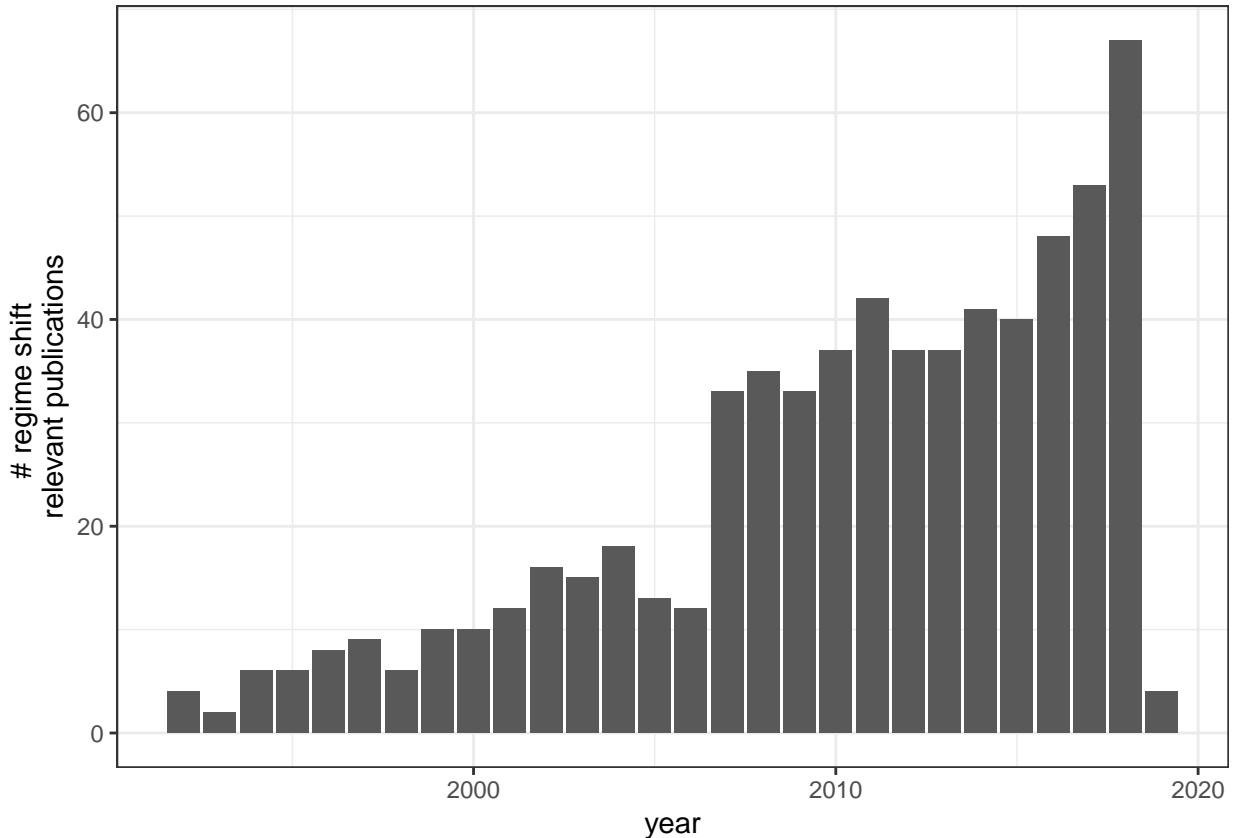

Figure 2.1: Number of publications by year in fields ‘Ecology’ and ‘Biodiversity Conservation’ which included terms related to ‘regime shift’ (total = 654).

⁴⁶³
⁴⁶⁴ related to ‘new method’ yielded 202 articles. After removing prior knowledge, only 93
⁴⁶⁵ articles remained to be reviewed ‘by hand’ (i.e., reading the entire paper). Of those
⁴⁶⁶ reviewed I identified 2 ‘new’ methods (2.3). Similarly, of the 250 articles reviewed
⁴⁶⁷ from the Google Scholar search, I retained only 3 methods. I was previously aware of
⁴⁶⁸ an additional 68 articles containing ‘new’ methods (2.3), approximately half of which
⁴⁶⁹ were identified using the abovementioned techniques.

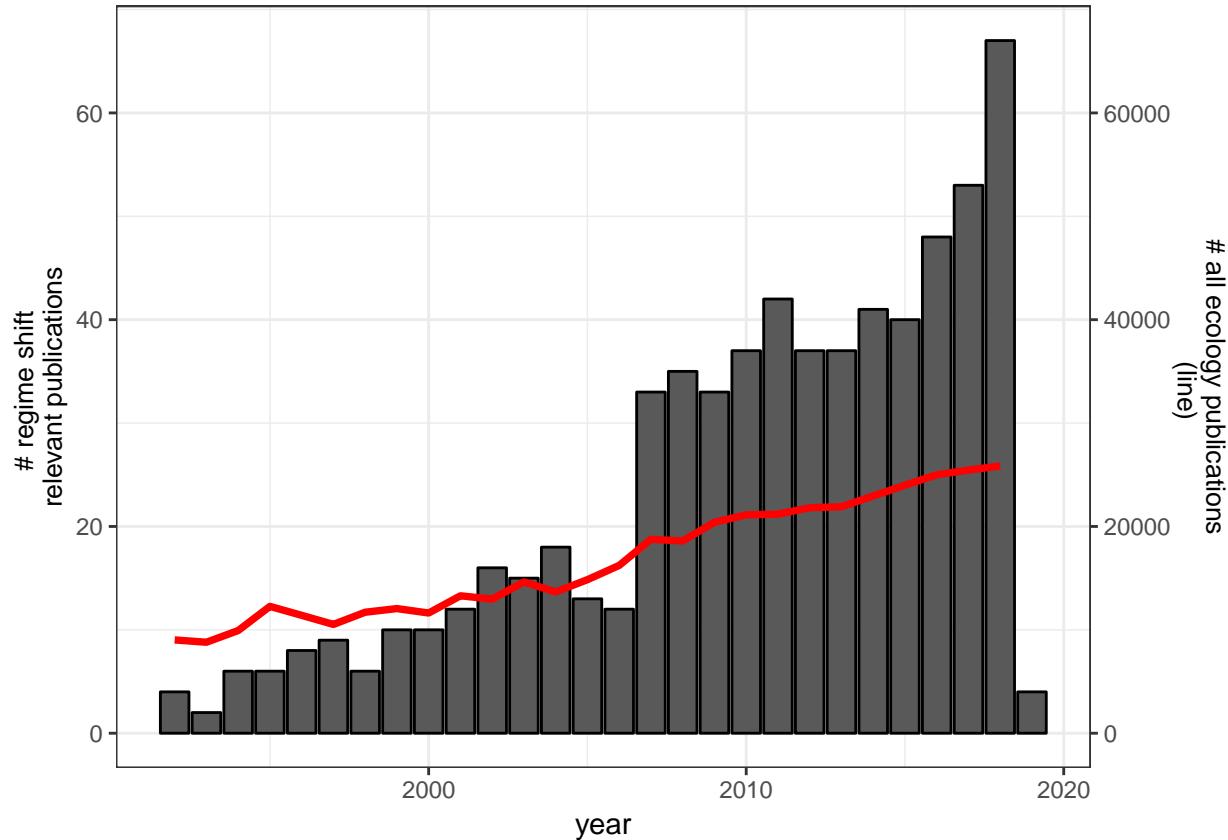

Figure 2.2: Number of publications by year in fields ‘Ecology’ and ‘Biodiversity Conservation’ which included terms related to ‘regime shift’ (total = 654).

470 Using my prior knowledge of the relevant literature and by systematically searching
 471 the Web of Science and Google Scholar databases, I identified 66 unique regime
 472 detection measures (Figure 2.3; Table ??).

473 2.4 Previous reviews of methods

474 Numerous reviews have summarised a portion of the RDMs proposed in the literature
 475 , and even fewer review the efficacy or robustness of many RDMs using real world
 476 ecological data. Further, these reviews are increasingly out-dated given the uptick
 477 in recent years of research articles focused on regime shift theory and detection. A
 478 permanent and open-source database containing information critical to the implemen-
 479 tation of RDMs would be a useful resource for those interested in applying RDMs but
 480 lacking the statistical or mathematical background to do so.

481 [S. N. Rodionov (2005); Roberts et al. (2018); Mantua (2004); Andersen et al.
 482 (2009); Dakos et al. (2015b); Mac Nally et al. (2014); Scheffer et al. (2015); Boettiger
 483 et al. (2013); Litzow & Hunsicker (2016);]
 484 (???: Ditlevsen & Johnsen, 2010)

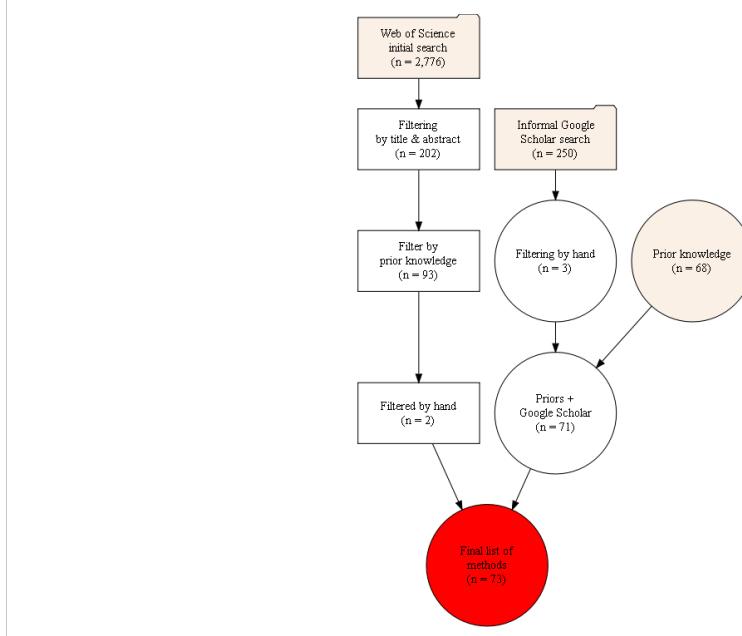

Figure 2.3: Flowchart of the literature review process for identifying new regime detection methods. *Only the first ten pages (250 articles) of Google Scholar results were examined. Node shapes: folder = unfiltered articles; box = articles actively filtered; diamond = number of articles with new methods.

485 Kefi et al. (2014); ; Clements & Ozgul (2018); Filatova et al. (2016); deYoung et
486 al. (2008)

487 It is thought by many that, should we assume a system exists in a statistically-
488 steady state, an abrupt shift can be identified prior to a system crossing a critical
489 threshold (or tipping point).

490 a synthetic review of these methods

491 2.5 A synthesis of the methods available for the 492 practical ecologist

493 Many of the methods identified in this review have yet to be tested on multiple,
494 empirical datum (see Table ??).

495 I categorize the regime detection methods as one of either model-free or model-

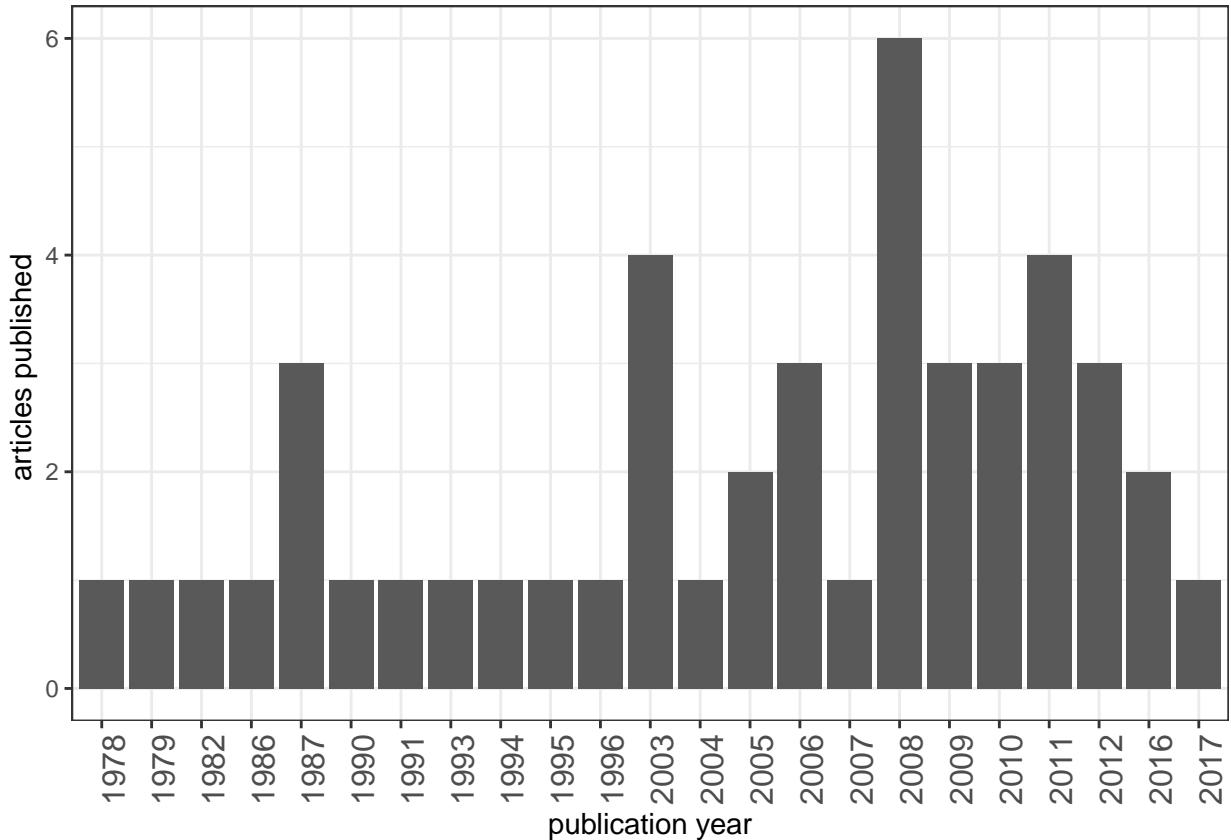

Figure 2.4: Number of methods published over time.

496 dependent. Model-free and model-dependent methods are those which do and do not
 497 require a mechanistic model to describe the system, respectively. Because many of
 498 the model-dependent methods are based on autoregressive modelling approaches, this
 499 is highlighted in the model-dependent section.

500 2.5.1 Model-dependent

501 Model-dependent require a mechanistic (mathematical) representation of the system,
 502 models which often carry strict assumptions that are easily violated by empirical
 503 systems (Abadi, Gimenez, Arlettaz, & Schaub, 2010). Model-dependent methods are
 504 usefully categorized under two contexts: differentiable systems of equations or
 505 autoregressive. The methods relying on mechanistic models include model descriptions
 506 of systems with many, dynamic and interacting components. For example, models are

507 used to reconstruct trophic food webs where prey or predator collapse induces trophic
508 regime shifts in freshwater lake systems (???: ???).

509 Autoregressive models have been used extensively in ecology to calculate the return
510 rate of an Among the most widely used RDMs includes return rate, which

511 2.5.2 Model-free

512 Model-free (or metric-based per Dakos et al. (2012)) methods are those which do not
513 require a mathematical representation of the system. In fact, many require much less
514 knowledge about the system component dynamics and their interactions to calculate a
515 results. The utility of these methods vary with respect to the number of state variables
516 encompassed in the method, and are therefore further categorized as either univariate
517 (using a single dimension) or multivariable (using but not necessarily requiring multiple
518 dimensions).

519 The most widely used model-free univariate RDMs include descriptive statistics
520 of individual system components (i.e. univariate), such as variance, skewness, and
521 mean value (Andersen et al., 2009; Mantua, 2004; S. Rodionov & Overland, 2005).
522 These univariate methods require only very simple calculations, however, their efficacy
523 in empirical systems analysis is controversial. For example, variance (Carpenter &
524 Brock, 2006) and skewness (of a single variable), oft referred to generally as ‘leading
525 indicators’ or ‘early-warning indicators’ in the literature, has been applied to both
526 theoretical and empirical systems data with varying results.

527 Hastings & Wysham (2010a) point out an important feature of using any methods
528 for identifying regime shifts in empirical system data: we only have a single history
529 within which we can compare AND these metrics which depend on the system exhibiting
530 a change in variance or skewness around a mean value before and after a regime shift
531 require the system to have a smooth potential, rather than one which can manifest
532 complex dynamics (i.e. non-smooth potential). If we are using RDMs to attempt to

533 forecast and prevent non-smooth or abrupt changes, then there is little justification for
534 relying upon these early warning indicators. Specifically, these early-warning indicators
535 may be most useful when the system is expected to undergo a transcritical or critical
536 bifurcation before exiting a regime (Lenton, 2011).

537 Hastings & Wysham (2010a) aptly point out that any realisitic ecological model
538 should include some degree of stochasticity, and when this stochasticity is introduced
539 into the function, the funciton will likely not be differentiable at the point of the
540 regime shift (Graham & Tél, 1984). If a function lacks a gradient along its range, then
541 leading indicators will most likely not indicate the abrupt change in system dynamics
542 alony any paramter.

543 takimoto2009early - SD, but not skewness and return rate, is a decent early warning
544 indicator in a system with Allee effects

545 Non-smooth potentials occur in a variety of sitautions, including those exhibiting
546 complex dynamics [@] or those having multiple attractors (???: Rinaldi, Muratori, &
547 Kuznetsov, 1993; Scheffer & Carpenter, 2003).

552 may be most useful when there is only a single or a few variables of interest, and
553 under the assumption that a change in variance For example, . Other univariate
554 descriptive statistics used include the

555 and composite measures (i.e. multivariable)

556 2.6 Conclusions

557 In this chapter I highlighted the plethora of regime detection metrics proposed in
558 the literature for analyzing ecological data (Table ??). Although multiple reviews
559 of regime detection measures exist, they are not comprehensive in their survey of
560 the possible methods. Most reviews have summarized various aspects of regime
561 detection measures. For example, Roberts et al. (2018) summarizes methods capable
562 of handling multiple (c.f. a single) variable, and Dakos et al. (2015b) review only
563 methods designed to detect the phenomenon of critical slowing down. Here, I did
564 not discriminate—rather, I present an exhaustive list of the methods proposed for
565 detecting ecological regime shifts, *sensu lato*, providing a much-needed update to
566 collection provided by S. N. Rodionov (2005), and other review papers (Mac Nally
567 et al., 2014, pp. @scheffer2015generic, @rodionov_brief_2005, @roberts2018early,
568 @dakos2015resilience, @mantua_methods_2004, @litzow_early_2016, @kefi2014early,
569 @andersen_ecological_2009, @boettiger_early_2013, @dakos_resilience_2015,
570 @clements2018indicators, @filatova2016regime, @deyoung_regime_2008).

571 Filtering In this review I restricted articles to those implying they introduced a
572 ‘new method’. Avoiding this potential barrier would have required I review the titles,
573 abstracts, and bodies of over 22,000 articles (Figure 2.3). Alternatively, this may also
574 be ameliorated by searching the relevant literature for *applications* of regime detection
575 measures to ecological data, however, I suspect this would similarly yield a large
576 number of articles to review. Also, only a handful of methods have been introduced to
577 the mainstream methodological journals in ecology (e.g., *Ecological Modelling*, *Methods*
578 in *Ecology and Evolution*; Figure 2.5). Although many mainstream publications (e.g.,
579 *Science*, *Ecology Letters*) include applications of some of the methods identified in
580 this chapter (Table ??), I argue that celebrity and ‘new and shiny’ (Steel, Kennedy,
581 Cunningham, & Stanovick, 2013) methods may influence which methodological articles
582 are printed in these popular journals. A critical survey of potential and realized

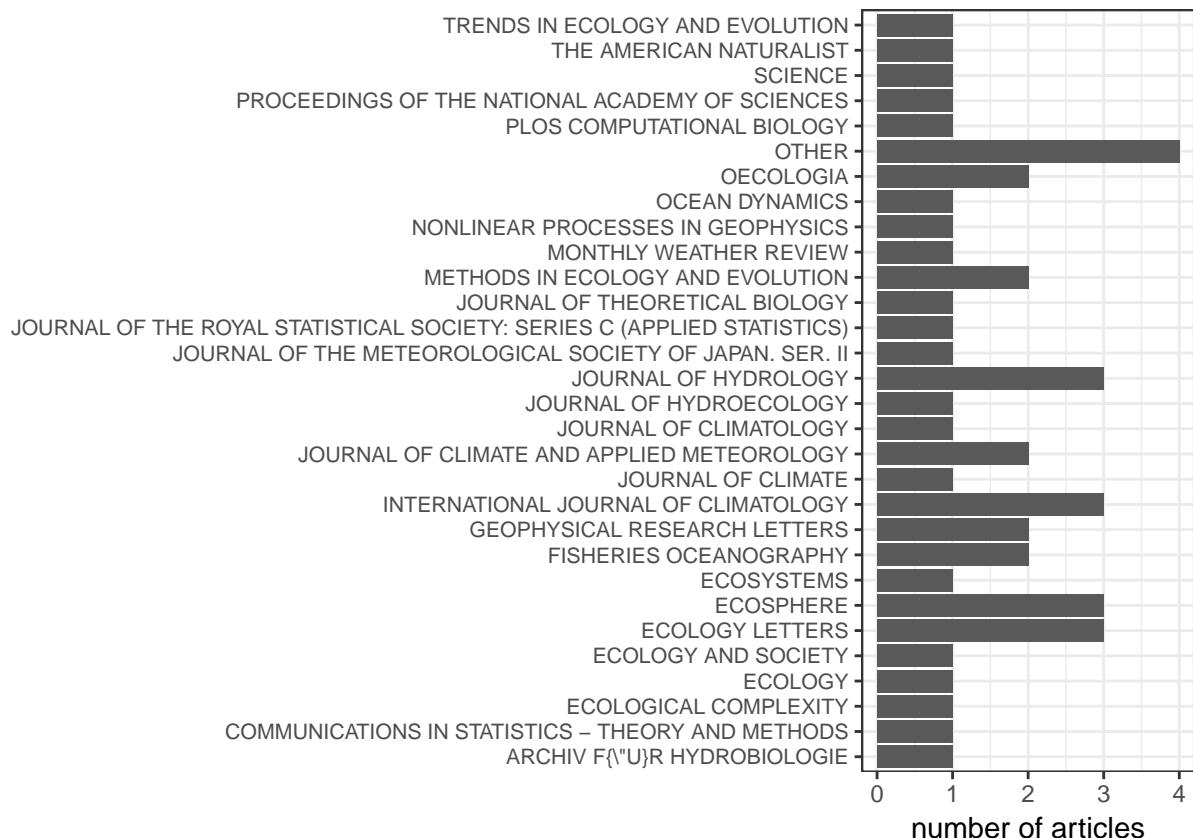

Figure 2.5: Distribution of identified methods across publications. Note: books, reports, and articles without original reference coded as ‘Other’

583 applications of these methods would be useful for highlighting the needs of future
 584 research and methodological improvements. Many of the methods presented in Table
 585 ?? have either not been applied to empirical data at all, or were tested only once,
 586 often but not always in the article introducing or adapting the methodology (Hawkins
 587 et al., 2015). Some methods, especially those dubbed ‘early warning indicators’
 588 (variance, autoregressive model coefficients) have become relativley mainstream in
 589 their application to empirical data, despite having been shown to be less robust in noisy
 590 and nonlinear systems (Burthe et al., 2016), in systems exhibiting lag-effects (Guttal,
 591 Jayaprakash, & Tabbaa, 2013), and in systems not exhibiting catstrophic shifts (Dutta,
 592 Sharma, & Abbott, 2018). Unlike these early warning indicators, fewer efforts have
 593 been made to test robustness under these and more simple conditions (Dutta et al.,

594 2018; c.f. Brock & Carpenter, 2010; Benedetti-Cecchi, Tamburello, Maggi, & Bulleri,
595 2015). In addition to the paucity of studies attempting to understand the limitations
596 of these methods, this review suggests that simply identifying the suite of methods
597 used in ecological regime shift detections may be difficult using traditional review
598 methods. Many of the methods mentioned in this review were not identified using a
599 systematic search process in Web of Science and Google Scholar—rather, they were
600 methods of which I was either previously aware and/or highlighted in the few methods
601 reviews (Andersen et al., 2009; Boettiger et al., 2013; Clements & Ozgul, 2018; Dakos
602 et al., 2015a, 2015b; deYoung et al., 2008; Filatova et al., 2016; Kefi et al., 2014;
603 Litzow & Hunsicker, 2016; Mantua, 2004; Roberts et al., 2018; S. N. Rodionov, 2005;
604 Scheffer et al., 2015). To facilitate this process, an online, comprehensive database
605 may prove useful to the practical ecologist.

606 2.6.1 Reducing the barriers to regime detection measures

607 To make the regime detection measures more available and transparent to the practical
608 ecologist, I recommend the following: 1. consistent use of fewer methods 1. persistent
609 collection and maintenance of baseline data (reference data) 1. an on-line database of
610 all methods - open-sourced - linked to the original sources (in ecology and statistics
611 or mathematics) - linked to applications 1. a critical review of the current state of
612 methods in ecology - including methodological advancements - especially highlighting
613 where the method fails to perform - including historical tracking of specific methods
614 to identify which may need to be retired, rather than resuscitated 1. more empirical
615 applications of these methods (especially of those only tested on toy and experimental
616 data) 1. relation of RDMs in ecology to other fields (computer science, data science,
617 climatology and oceanography)

618 I suggest below (Table 2.3) a suite of questions which may be useful in a critical
619 review of the characteristics, rigor, and promise of methods in the context of ecological

⁶²⁰ regime shift detection.

Table 2.3: Potential questions for a comprehensive review of the ecological regime detection metrics literature.

Type	Questions
Methodological	<p>Does the regime shift need to be identified <i>*a priori*</i>?</p> <p>What are the major assumptions about the distribution of the original data?</p> <p>Does the method explicitly assume the system/variable is stationary?</p> <p>Does the performance of the method change with non-stationarity?</p> <p>Can the method handle unstructured data?</p> <p>Can the method handle multiple regime shifts?</p> <p>What types of regime shifts can the method detect (e.g., stochastic resonance, slow-fast cycles, noise-induced transition)?</p> <p>Is it a model- or metric-based method?</p> <p>Does it have forecasting potential?</p> <p>Can the method handle uneven sampling?</p>
Ecological	<p>What are the minimum data requirements (resolution, extent, number of observations)?</p> <p>How does the method handle missing data (e.g., new invasions)?</p> <p>Does the method assume Eulerian or Lagrangian processes?</p> <p>Has the method been tested on empirical data? If so, to what rigor?</p> <p>What is the impact of losing state variables on long-term predictions (e.g., species extinction)?</p> <p>Can the method identify drivers?</p> <p>What assumptions does the method make about the system?</p> <p>What types of regime shifts are possible in the system?</p>

- Are regime shift(s) suspected *a priori*?
 - What lag(s) exist in the data (system)?
 - Would a positive forecast change management action?
 - Do predictions translate to other systems?
 - Can we interpolate data if necessary? If so, what does this mean for inference?
 - In which discipline(s) beyond ecology has the method been tested?

624 *This chapter is intended for submission to the publication Methods in Ecology and*
625 *Evolution.*¹

626 **3.1 Abstract**

627 Ecological regime shifts are increasingly prevalent in the Anthropocene. The number
628 of methods proposed to detect these shifts are on the rise yet few are capable detecting
629 regime shifts without a priori knowledge of the shift or are capable of handling high-
630 dimensional and noisy data. A variation of Fisher Information (FI) in a dataset was
631 proposed as a method for detecting changes in the orderliness of ecological systems.
632 Although FI has been described in multiple research articles, previous presentations do
633 not highlight a key component of FI that may make the metric easier to understand
634 by practitioners. I used a two-species predator prey model to describe the concepts
635 required to calculate FI. I hope this work will serve as a useful explanation of the FI
636 metric for those seeking to understand it in the ecological systems and regime shifts.

637 3.2 Introduction

638 Changes in the feedback(s) governing ecosystem processes can trigger unexpected and
639 sometimes undesirable responses in environmental conditions (Scheffer, Carpenter,
640 Foley, Folke, & Walker, 2001; Walther et al., 2002). Ecologists often refer to such
641 changes as regime shifts, but this term is used interchangeably in the literature with
642 state change, state transition, or alternative state (Andersen et al., 2009). Climate
643 change and globalization are triggering novel and unexpected changes in ecosystems,
644 and the rapidity with which these changes occur make predictive modeling difficult.
645 Although detecting regime shifts becomes more difficult as one increases the extent
646 and complexity of the system in question , advances in the collection and analysis of
647 ecological data may improve our ability to detect impending regime shifts in time for
648 intervention (Jorgensen & Svirezhev, 2004).

649 Although multiple quantitative approaches are proposed as regime shift detection
650 methods ,few are consistently applied to terrestrial ecological data. I classify a regime
651 shift detection methods (DMs) broadly as either model-based or model-free (Boettiger
652 & Hastings, 2012; Dakos et al., 2012; Hastings & Wysham, 2010b). Model-based
653 methods incorporate mathematical (mechanistic) representations of the system (Hefley,
654 Tyre, & Blankenship, 2013) and carry strict assumptions, which are often violated by
655 real systems (Abadi et al., 2010). In addition to assumption violations nullifying parts
656 of the model, model misspecification may yield spurious results (Perretti, Munch, &
657 Sugihara, 2013).

658 Model-free (or metric-based detectin ethods (e.g., descriptive statistics, cross-
659 correlation mapping) require fewer assumptions to implement than do model-based
660 DMs (Dakos et al., 2012). The most widely used model-free methods for detecting
661 ecological regime shifts include descriptive statistics of one or a few components
662 of a system, such as variance, skewness, and mean value (Andersen et al., 2009;
663 Mantua, 2004; S. Rodionov & Overland, 2005) and composite measures which handle

664 multivariable data, including principal components analysis (Petersen et al., 2008),
665 clustering algorithms (Beaugrand, 2004), exergy (Fath & Cabezas, 2004), and Fisher
666 Information (Cabezas & Fath, 2002; Karunanithi, Cabezas, Frieden, & Pawlowski,
667 2008).

668 Fisher Information, hereafter FI is a model-free composite measure of any number
669 of variables (Fisher, 1922), and is proposed as an early warning signal for ecological
670 regime shift detection system sustainability (Mayer, Pawlowski, Fath, & Cabezas,
671 2007, p. @karunanithi_detection_2008, Eason and Cabezas 2012, Eason et al. 2014a).
672 Three definitions of FI exist: 1. A measure of the ability of the data to estimate a
673 parameter.

- 674 1. The amount of information extracted from a set of measurements (Roy Frieden,
675 1998).
- 676 1. A measure representing the dynamic order/organization of a system (Cabezas &
677 Fath, 2002).

678 The application of FI to complex ecological systems was posed as part of the
679 ‘Sustainable Regimes Hypothesis,’ stating a system is sustainable, or is in a stable
680 dynamic state, if over some period of time the average value of FI does not drastically
681 change (Cabezas & Fath, 2002). This concept can be described using an ecological
682 example. Consider the simple diffusion of a population released from a point source at
683 $t = 0$. This process can be described by a bivariate normal distribution, $p(x, y|t)$. As
684 the time since release (as t increases) increases the spread of the distribution, $p(x, y|t)$,
685 becomes larger (less concentrated about the mean) because the animals have moved
686 further from the release location. FI will decrease in value as t increases, because
687 $p(x, y|t)$ contains less information (higher uncertainty) about where the animals will
688 be located. As $t \rightarrow \infty$, the animals will be relatively uniformly distributed across the
689 environment and $p(x, y|t)$ will carry no information about the location of the animals.
690 Consequently, as $t \rightarrow \infty$, FI will approach zero. This system is not in a stable dynamic

691 state because FI is decreasing with time.

692 In contrast, imagine a population varying around a carrying capacity following
693 a simple logistic growth model. As long as the average system parameters (r and K
694 and their variances) are stationary (not changing with time), then the logarithm of
695 population size will have a normal distribution (check this!!!might need some different
696 model). The FI measured over any selected window of time will be constant, indicating
697 that the system is in a stable dynamic state. A perturbation to the population size due
698 to disturbance will also not affect FI, as long as the disturbance does not change the
699 distributions of r and K , and the perturbations themselves occur with some stationary
700 probability distribution.

701 Although the concept of FI is firmly grounded in physics (Frieden, 1998), the
702 concepts behind its application to ecological systems remain elusive to the average
703 ecologist. I aim to elucidate the statistical concept of FI and the steps required to
704 calculate it as a measure of ‘ecosystem order’ and as a regime shift detection method
705 (Cabezas & Fath, 2002; Fath, Cabezas, & Pawlowski, 2003). I believe a concise and
706 accessible synthesis of the topic, along with reproducible code, will aid the ecologists’
707 understanding of this metric and will advance our understanding of its usefulness as
708 an indicator of ecological regime shifts. I reproduce the analyses presented in (Fath
709 et al., 2003) and Mayer et al. (2007) to fully explain these concept of and steps for
710 calculating this form of Fisher Information. I hope this work will serve as a useful
711 explanation of the FI metric for those seeking to understand it in the ecological regime
712 shift context and will stimulate research using this and other multivariate, model-free,
713 and composite measures to understand ecological regime shifts.

714 3.2.1 On Fisher Information

715 Two methods exist for calculating Fisher Information (FI) as applied to ecological
716 systems data, which I refer to as the *derivatives-based* method, first appearing in

⁷¹⁷ Cabezas & Fath (2002), and the *binning* method, first appearing in Karunanithi et al.
⁷¹⁸ (2008). The binning method was proposed as an alternative to the derivatives-based
⁷¹⁹ method for handling noisy and sparse data, and requires additional calculations and
⁷²⁰ system-specific decisions, and for these reasons I focus solely on the derivatives-based
⁷²¹ method. The general form of FI can be found in (Fath et al., 2003) and (Mayer et al.,
⁷²² 2007), and although others can be found, I refer the reader to Cabezas & Fath (2002)
⁷²³ for a complete derivation of FI.

⁷²⁴ 3.2.2 Notation

⁷²⁵ A capital letter (e.g., A) denotes a random variable; an asterisk superscript (*) indicate
⁷²⁶ a particular realization; *bold notation* indicates that the state of the system is defined
⁷²⁷ in more than one dimension.

⁷²⁸ 3.2.3 Steps for calculating Fisher Information (FI)

⁷²⁹ To calculate FI for a system with more than one state variable, I first estimate the
⁷³⁰ probability of observing the system $p(x)$ in a given state, x , over time period T . The
⁷³¹ probability density function, $p(x)$, is then directly used to calculate the derivatives-
⁷³² based FI. I use bold notation to indicate that the state of the system is defined in
⁷³³ more than one dimension (e.g., the state of a predator prey system is defined in two
⁷³⁴ dimensions by the number of predators and number of prey). Here, I describe these
⁷³⁵ steps and present the numerical calculation of FI using a two-species predator-prey
⁷³⁶ model [Fath et al. (2003); mayer_applications_2007], hereafter referred to as the
⁷³⁷ ‘model system’:

$$dx_1 = g_1 x_1 \left(1 - \frac{x_1}{k}\right) - \frac{l_{12} x_1 x_2}{1 + \beta x_1} dx_2 = \frac{g_{21} x_1 x_2}{1 + \beta x_1} - m_2 x_2 \quad (3.1)$$

⁷³⁸ The specified parameters for the model system are $g_1 = m_2 = 1$, $l_{12} = g_{12} = 0.01$,
⁷³⁹ $k = 625$,and $\beta = 0.005$ (see Fath et al., 2003; Frieden & Gatenby, 2007; Mayer et al.,
⁷⁴⁰ 2007). The initial conditions (predator and prey abundances) for the model system
⁷⁴¹ were not provided in the original references. Using package *deSolve* in Program R
⁷⁴² (v 3.3.2) to solve the model system (3.1) I found $x_1 = 277.7815$ and $x_2 = 174.551$
⁷⁴³ provided reasonable results. I found that a complete cycle of the system corresponds
 to approximately 11.145 time units.

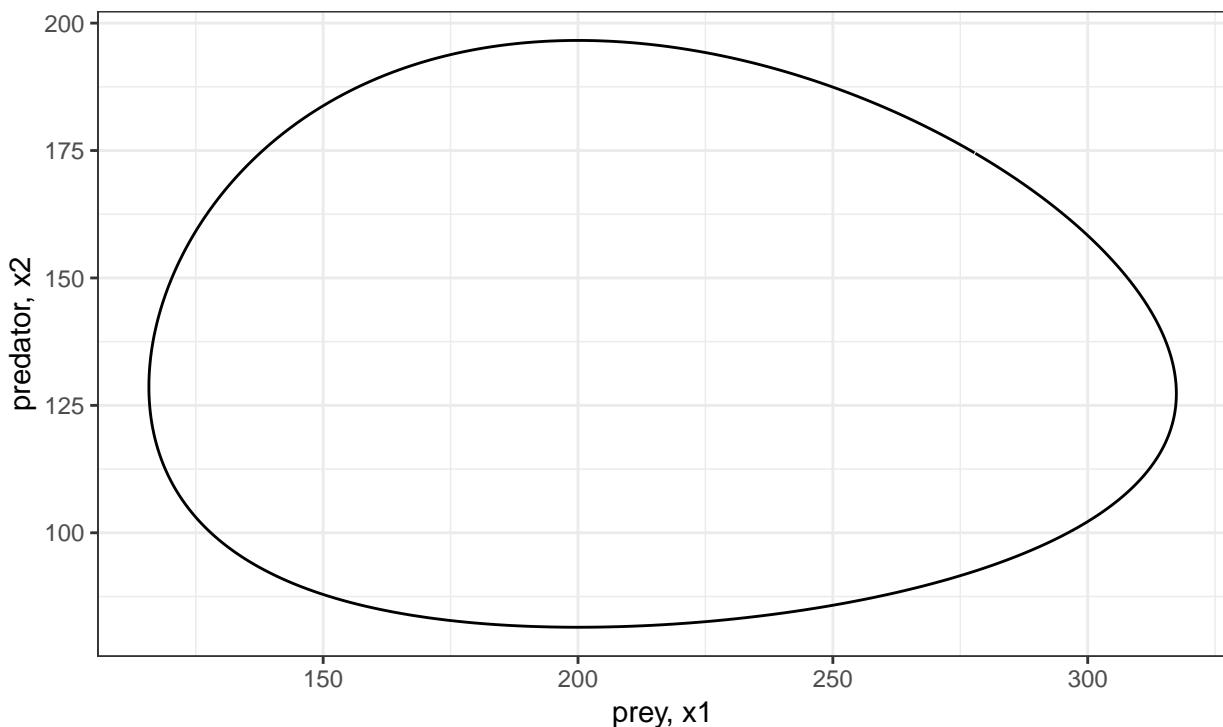

Figure 3.1: Phase space plot of two-species Lotka-Volterra predator-prey system over a single period (~11.145 time units).

⁷⁴⁴

⁷⁴⁵ 3.2.4 Concepts behind the calculations

⁷⁴⁶ Although the numerical steps for calculating the derivatives-based FI are relatively
⁷⁴⁷ straightforward, the concepts required to interpret the measure in the context of
⁷⁴⁸ multiple variables is more complex. Here, I thoroughly discuss the concepts and
⁷⁴⁹ assumptions behind FI calculation. Below, steps do not represent steps within the

750 calculation, they represent the major concepts required

751 **Step 1. Probability of observing the system in a particular state, $p(x)$**

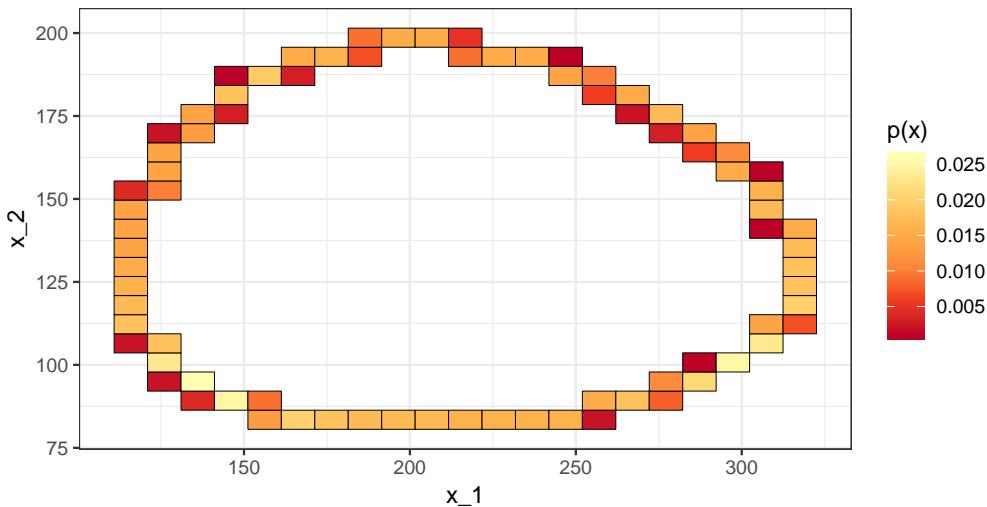

Figure 3.2: A 2-dimensional histogram of the probability of observing a system in a particular state, $p(x)$, of the 2-species Lotka-Volterra predator prey system over a single period (11.145 time units).

752 Fisher Information (FI) is defined with respect to a probability distribution. In the
 753 derivatives-based method, FI is calculated for a probability of observing a system (as
 754 defined by one or more state variables) in a particular state, $p(x)$, over some period
 755 of time, ($0 \text{to} t_{end}$). In other words $p(x)$ is the probability that, at a specific point in
 756 time (t_{obs}^*) we will observe the system in a particular state, x^* . The time at which we
 757 observe the system is a random variable, $t_{obs} \sim Uniform(0, t_{end})$. To be clear, the study
 758 system is assumed to be deterministic and we assume no observation error, however,
 759 the observed state of the system, $x(T_{obs})$, is a random variable because it is a function
 760 of the random observation time, $x^* = x(t_{obs}^*)$. The state of the model system, x , is
 761 defined in two dimensions by the number of predators and the number of prey (3.1)
 762 and is easily visualized 3.1. Therefore, the probability of observing a particular state is
 763 a two-dimensional joint distribution ??.

764 A single state of the model system is defined by the number of predators and prey

at a given point in time such that for any given point in time $x(t) = [x_1(t), x_2(t)]$.
 At some random time between 0 and t_{end} [$T_{obs} \sim Uniform(0, t_{end})$] we can count the
 number of predators and the number of prey to determine the state of the model
 system. We must assume the system is deterministic and there is no observation error.
 We can then calculate the probability of observing a particular predator and prey
 abundance combination, $p(x)$. Under these assumptions, the only possible states of
 the system are defined by the system's observed trajectory, the model parameters,
 and the initial conditions. Therefore, the support of the probability distribution 3.2 is
 the trajectory of the system.

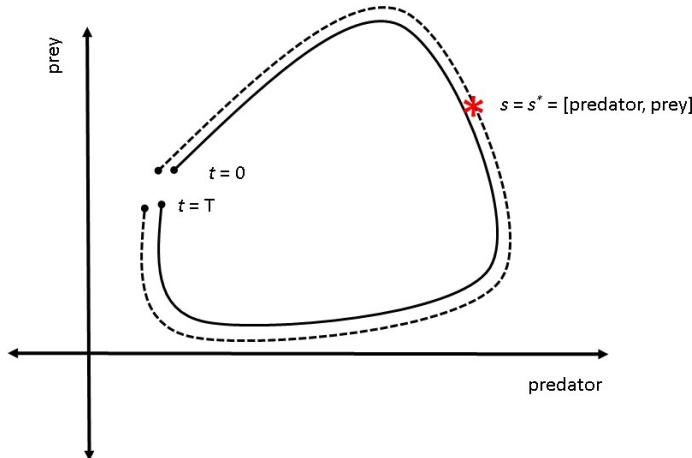

Figure 3.3: A single cycle of a hypothetical two-species system over time period $t = 0$ to $t = T$. s^* is the state of the system at some point in time. The dotted line represents the distance travelled by the system in phase space over its trajectory during $(0, T)$.

773

774 Step 2. Distance traveled by the system, s

Distance traveled by the system, s . We can now move from an n-dimensional representation of the probability distribution to a one-dimensional representation. To better understand this, imagine placing a string over the path of the entire trajectory from

778 $0 \text{ to } t_{end}$ 3.3. If we know the number of predators and prey at a particular point in time
779 (t_{obs}^*) then we can mark that location on the string (see asterisk in 3.3. Next, imagine
780 picking up the string and laying the string flat along a ruler. The length, s , of the
781 entire string measures the total distance traveled by the system in phase space. The
782 mark we made on the string (denoted *) lies at a distance s^* between 0 and s . We call
783 this length the distance traveled by the system, s^* . In this context, s^* in phase space
784 represents a measure of cumulative change in state. We note that the distance traveled
785 in phase space increases monotonically with time. If the system never revisits the same
786 state (i.e., the trajectory never overlaps or intersects itself), then every unique system
787 state (i.e., point on the trajectory) is mapped to a unique value of distance traveled.
788 Therefore, $p(x)$ (n-dimensional) is equivalent to the probability that the system is
789 at distance s , i.e., $p(x) = p(s)$, (where $p(s)$ is one dimensional; Cabezas, Pawlowski,
790 Mayer, & Hoagland (2005)). However, if the system revisits previous states, then
791 a unique system state may be mapped to different values of distance traveled and
792 the relationship between $p(x)$ and $p(s)$ is not one-to-one. We calculated the distance
793 traveled s of the model system over a single cycle (11.145 time units; 3.4.

794 **Step 3. $p(s)$ as a function of the rate of change of s**

795 In previous presentations of FI, the relationship between the state of the system
796 (n-dimensional) and the distance traveled (1-dimensional) was not always emphasized
797 (Cabezas & Fath, 2002). Here we use x to denote the state of the system and s to
798 denote the distance traveled to emphasize this distinction. If a system travels at a
799 constant speed over the entire time period, then the system is equally likely to be in
800 any state along the trajectory (s is linear and $p(s)$ is uniform). Referring to our model
801 system, if the number of predators and prey are linearly related, then the speed of the
802 system is constant. For non-linear systems, the distribution above the string will not
803 be uniform 3.3. Rather, it will change depending on the amount of time the system

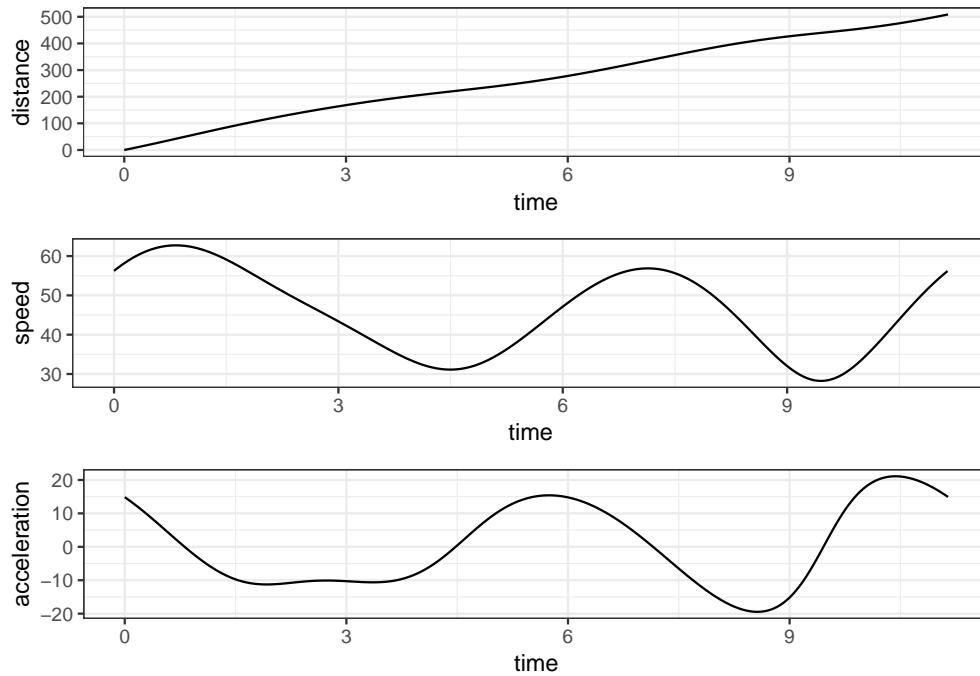

Figure 3.4: From top to bottom, distance traveled in phase space, speed tangential to system trajectory, acceleration tangential to system trajectory.

spends in each state. It follows that $p(s)$ is proportional to the inverse of the rate of change of distance traveled (i.e., the speed along the path in phase space).

We will now demonstrate this using our model system as an example. Suppose the abundances of the predator and their prey in our model system predictably operate at carrying capacity. Over a relatively short period of time the prey abundance quickly declines after a severe weather event (a pulse disturbance; (Bender et al. 1984), but quickly recovers. Intuitively, the absolute rate of change at time points near the disturbance will be larger than during time periods long before or long after the disturbance. It is therefore more likely that the system will be (observed) in a state where prey and predators are operating approximately at carrying capacity than in a state with relatively low prey abundance. Mathematically, the time, t^* , at which we calculate the abundances of prey and predators is a uniform random variable, and the distance traveled by the system, s^* , is a function of time, is differentiable, and monotonically increases. Therefore, the probability density function of the distance

818 traveled $p(s) = \frac{1}{T} \frac{1}{s'}$, where $s' = \frac{ds}{dt}$ is the speed of the system (the speed tangential
 819 to the trajectory; the first derivative of the distance traveled; instantaneous rate of
 820 change of s). We calculated the speed (the first derivative; 3.4 and acceleration (the
 821 second derivative; 3.4 of the distance traveled s by the model system over a single
 822 cycle using function `ode` in package `deSolve` (Soetaert et al. 2010) in Program R (R
 823 Core Team 2016).

824 **Step 4. Calculate the derivatives-based Fisher Information**

825 Now that we understand how to calculate both the distance traveled, s , and its
 826 probability density, $p(s)$, calculating the derivatives-based FI is straightforward and
 827 computationally inexpensive (4.4). There are several comparable equations for calcu-
 828 lating the shift-invariant FI, and some may offer numerical advantages over others.
 829 Equation (3.3) is the general form and Equation (3.4) is the amplitude form for FI (in
 830 Mayer et al. (2007), respectively). Although these formulations are equivalent, (3.4)
 831 is most readily calculated when the differential equations for the system are known,
 832 obviating any advantage of a model-free metric.

$$I = \frac{1}{T} \int_0^T dt \left[\frac{s''^2}{s'^4} \right]^2 \quad (3.2)$$

$$I = \int \frac{ds}{p(s)} \left[\frac{dp(s)}{ds} \right]^2 \quad (3.3)$$

$$I = 4 \int ds \left[\frac{dq(s)}{ds} \right]^2 \quad (3.4)$$

833 This article is interested in the Fisher Information calculated for a distribution of
 834 distance traveled, s , by the entire system. We calculated the Fisher Information value
 835 using Equation (4.4) over a single period of the model system ((3.1)). We calculated
 836 Fisher Information to be 5.3×10^{-5} which is consistent with the results of Mayer et
 837 al. (2007).

840 3.3 Case Study

841 Mayer et al. (2007) calculated FI for a predator-prey system for several discrete
 842 values of carrying capacity of prey. The results of this study showed that FI
 843 was different for systems with different carrying capacities. However, this study
 844 did not address the central question of how FI changes during a regime shift.
 845 As an extension of the original study, we simulate a regime shift by modeling a
 846 situation where carrying capacity is abruptly decreased. To simulate an abrupt
 847 change in carrying capacity, we assume carrying capacity is described by Eq. 6
 848 where k_1 is the initial carrying capacity, k_2 is the final carrying capacity, t^* is
 849 the time of the regime shift, and alpha is a parameter that controls how quickly
 850 the regime shift occurs. The hyperbolic tangent function simulates a smooth,
 851 continuous change in carrying capacity while still allowing for the change to
 852 occur suddenly. To incorporate the change in carrying capacity into the system
 853 differential equations we define the rate of change of carrying capacity as given by (3.5).

854

$$k(t) = k_1 - 0.5(k_1 - k_2)(\tanh(\alpha(t - t^*)) + 1) \quad k'(t) = 0.5\alpha(k_1 - k_2)(\tanh(\alpha(t - t^*))^2 + 1) \quad (3.5)$$

855 We assumed an initial carrying capacity of 800 and a final carrying capacity of 625
 856 which corresponds to the range of carrying capacities explored by Mayer et al. (2007).
 857 We simulated a time series of 600 time units with a regime change after 200 time
 858 units. We used an alpha value of 0.05. The time series for carrying capacity is
 859 shown in 3.5 and the system trajectory in phase space is shown in 3.6. The distance
 860 travelled in phase space (i.e., cumulative change in state) is shown in ?? and the
 861 speed of the system (i.e., rate of change) is shown in 3.7. We calculated FI for
 862 the distribution of distance travelled over a series of non-overlapping time windows.
 863 Multiple sources suggest the length of the time window should be equal to one system
 864 period such that FI is constant for a periodic system (Cabezas & Fath, 2002; Mayer

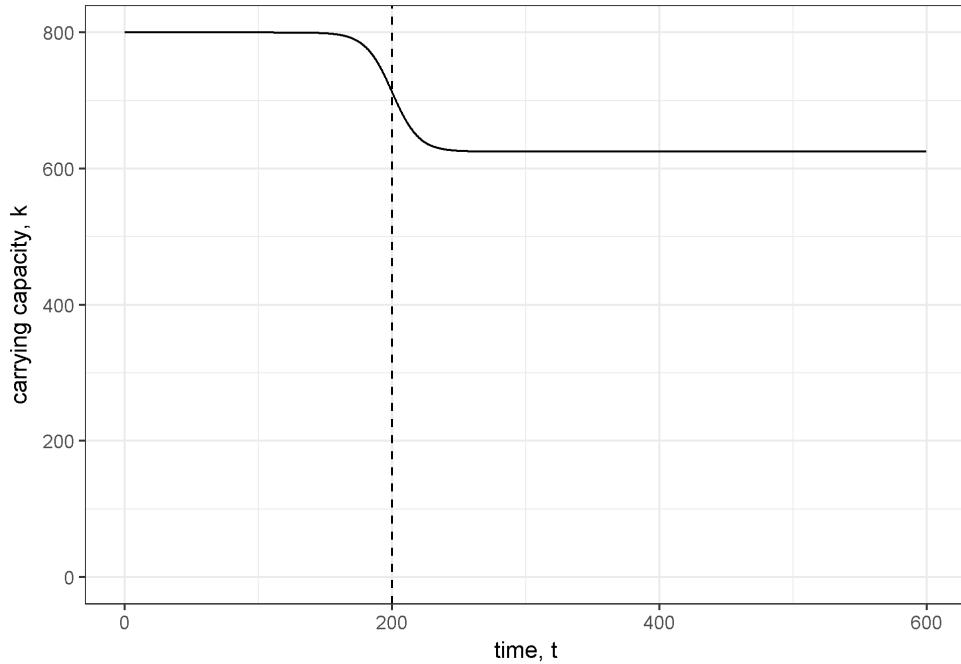

Figure 3.5: Carrying capacity over time with a regime shift occurring around time 200.

et al., 2007). However, the system period is different before, during, and after the regime shift. Therefore, we performed two separate calculations of FI using window sizes corresponding to the initial and final period of the system (13.061 and 11.135, respectively). The change in FI over time is shown in 3.8.

3.4 Conclusions

We simulated a regime shift caused by a change in carrying capacity (K) within a simulated, two-species Lotka-Volterra system. I applied the Fisher Information (FI) method for regime shift detection to the simulated time series data. The predator-prey system was modeled as deterministic and the time series data was free from measurement and observation error. Despite this, the estimated FI had high variation over time, and results were dependent on the size of the time window used (winsize) in the calculation 3.8. The FI method for regime shift detection is based on the

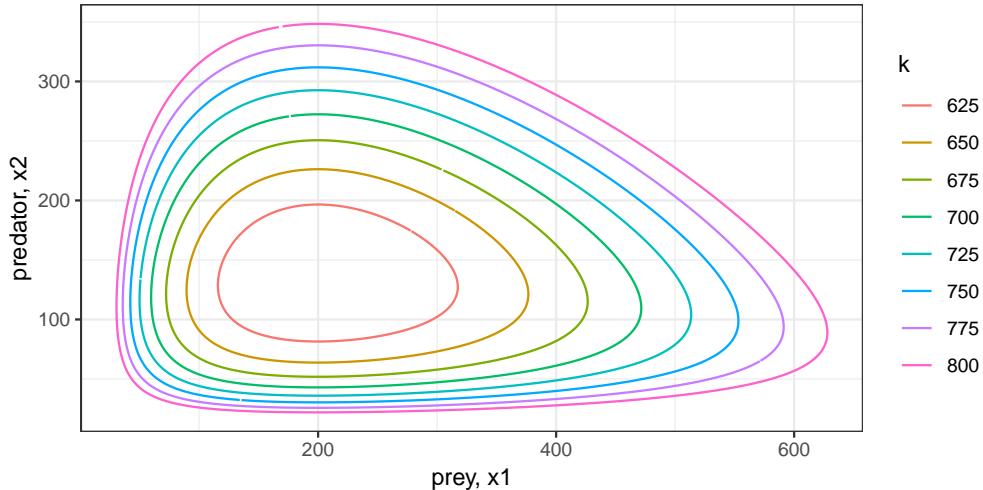

Figure 3.6: Phase space plot of system trajectories for different values of k

877 cumulative change in the state of the system (i.e., distance traveled in phase space)
 878 and the rate of change of the system (i.e., speed tangential to trajectory in phase
 879 space). The distance travelled metric, s , and its speed, $dsdt$, appear better visual
 880 indicators of the regime shift than FI [??; 3.7].

881 In our explanation of the FI concept and calculation, I emphasize the distinction
 882 between the *state of the system* and the *distance traveled in phase space*. There
 883 are several reasons worth emphasizing this. First, there may not always be a one-
 884 to-one relationship between the probability of observing a system in a particular
 885 state and the probability of observing a system at a particular distance along the
 886 trajectory. In these situations the interpretation of FI may be less clear than if a
 887 one-to-one relationship existed. Second, this distinction facilitates the separation of
 888 the dimensionality reduction step (calculating distance traveled in phase space, s)
 889 from the subsequent steps related specifically to FI. Third, the distinction suggests
 890 that the **value of FI as a regime shift detection method is related to the**
 891 **rate of change of the system** (i.e., velocity and acceleration tangential to system
 892 trajectory in phase space). In particular, the distribution for which FI is calculated is
 893 simply the distribution of the distance traveled in phase space, when time is assumed

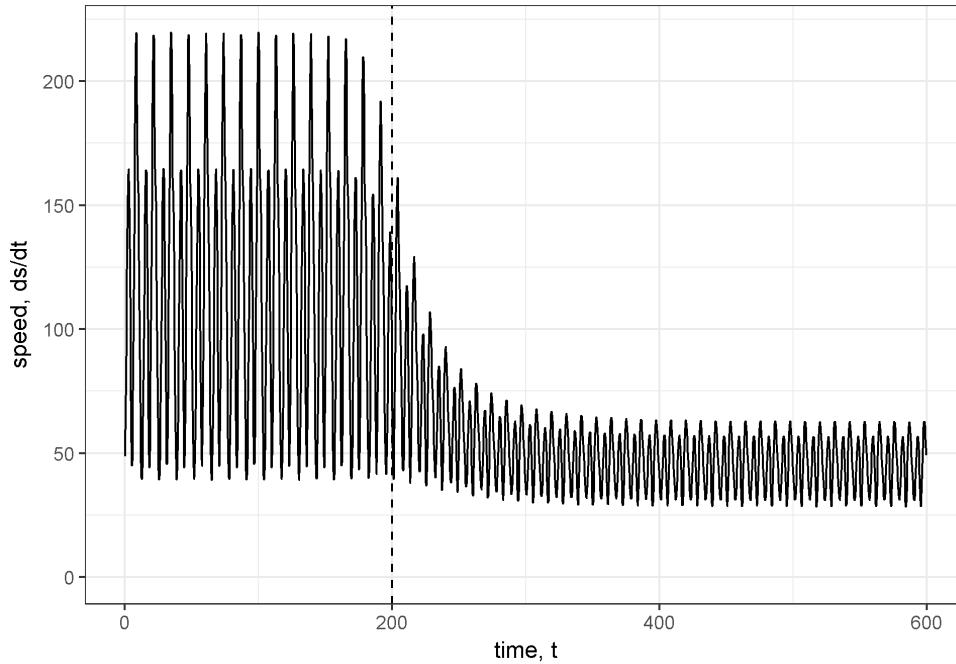

Figure 3.7: Speed of the system (rate of change) in phase space. Dashed vertical line at time 200 indicates location of regime shift.

894 to be uniformly distributed over a given interval.

895 Our results suggest that insights can be gained directly from the calculation of
896 distance traveled and associated rates of change. Consequently, these insights preclude
897 the need to calculate beyond Step 3 (described above). This result also supports the
898 use of the distance travelled metric, or the derivatives-based Fisher Information .

899 One remaining issue that is prevalent across ecological field studies is the assumption
900 that the system is observed without error. Although ecological data rarely fulfill this
901 assumption, this does not suggest that FI is useless as a metric of system stability.
902 The primary difficulty with noisy data, especially with observations in integer form
903 (e.g. count data), is that the denominator in can easily be zero for some pair of
904 observations, making FI an infinite value within windows which contain two or more
905 adjacent zero observations. One possible solution is to smooth the multidimensional
906 vector of observations prior to calculating the derivatives, or to treat any sequential
907 identical value as missing, and simply use a larger time step for that portion of the

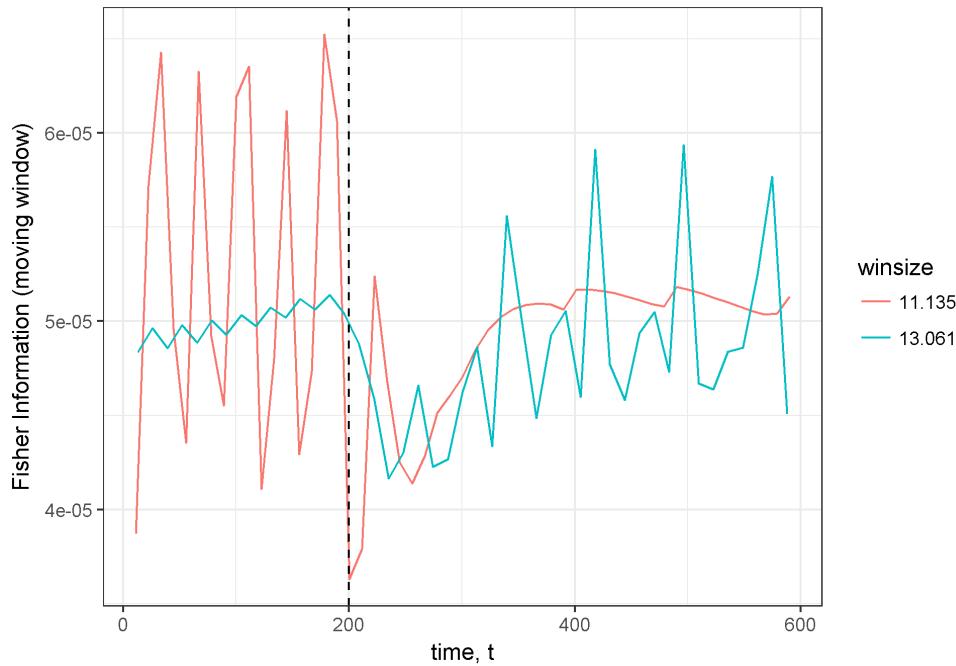

Figure 3.8: Fisher Information calculated for non-overlapping time windows. Two different window sizes were used as indicated by color. Dashed vertical line at time 200 indicates approximate location of regime shift.

908 window calculation.

909 The utility of Fisher Information in ecological studies is also stunted by its in-
 910 terpretability. This metric is unitless, making its values relative only within-sample
 911 (e.g., within a single time series). Further, interpreting the results within-sample is
 912 currently a qualitative effort (Fath et al., 2003; Mantua, 2004). When the FI of a
 913 system is increasing, the system is said to be moving toward a more orderly state, and
 914 most presentations of FI posit sharp changes in FI, regardless of the directionality of
 915 the change, may indicate a regime shift (Cabezas & Fath, 2002; Karunanithi et al.,
 916 2008; Spanbauer et al., 2014). Due to the qualitative nature of these interpretations
 917 of Fisher Information, intimate knowledge of the system in question and the potential
 918 driver(s) of the observed regime shift are required to confirm presence of a shift.

⁹²³ An application of Fisher

⁹²⁴ Information to spatially-explicit

⁹²⁵ avian community data

⁹²⁶ 4.1 Introduction

⁹²⁷ Ecosystems are open, dynamical systems which arguably cannot be fully represented by
⁹²⁸ deterministic models. Despite the complexity of most ecological systems, some patterns
⁹²⁹ have emerged in certain statistical mechanics of ecological observations. An uptick in
⁹³⁰ recent years of studies of **regime shifts** (??) in ecology has spurred an increase in
⁹³¹ the number of ‘new’ methods for detecting ecological regime shifts (2), some of which
⁹³² are proposed as indicators of ‘spatial’ regime shifts (Butitta, Carpenter, Loken, Pace,
⁹³³ & Stanley, 2017, pp. @kefi2014early, @sundstrom2017detecting, @guttal2009spatial,
⁹³⁴ @brock_variance_2006).

⁹³⁵ As defined in ??, a regime shift is largely considered an abrupt and persistent
⁹³⁶ change in a system’s structure or functioning. Following this definition and without
⁹³⁷ any associated **pressures** ??, it is not yet clear whether identifying a ‘spatial regime’

938 using a snapshot of a system (a single or short period of time relative to the time
939 scale of the pressure) is pragmatic. One spatial regime detection measure (hereafter,
940 SRDM) is variance (Brock & Carpenter, 2006), despite its controversial applicability
941 to temporal data (???).

942 Defining the spatial regime shift is important since observations of non-random
943 spatial processes (e.g., land cover), could manifest as either rapid shift (e.g. an ecotone)
944 or a gradual change (slow mixing along a gradient). Consequently, and because most
945 RDMS signal abrupt change, only the former may be identified as “regime shifts”
946 using SRDMs. For the concept of spatial regimes to be ecologically useful, potential
947 pressures must be associated with system structure over space *and* time. Additionally
948 and perhaps more importantly, the processes driving the observed information (drivers,
949 pressures) should be such that a statistically identified regime shift will roughly
950 correspond with the time scale on which the pressure(s) operate.

951 Although it is suggested that statistical and pragmatic models and methods are
952 advanced more rapidly by bottom-up approaches, i.e. case studies (see DeAngelis
953 & Yurek, 2017), to my knowledge no studies have yet to test the rigor of SRDMs
954 using spatially-explicit empirical data. The objective of this chapter is to determine
955 the utility of Fisher Information (Eq. (4.4)) as a spatial regime detection measure.
956 This chapter is also supported by original software developed for implementation in
957 Program R, which is publicly available [see Appendix ??].

958 4.2 Data and methods

959 4.2.1 Data: North American breeding bird communities

960 I use community abundance data from long-term monitoring programs to identify
961 spatial and temporal regimes using the Fisher Information (FI) derivatives method
962 (see Eq. (??)). The NABBS trains citizen scientist volunteers to annually collect

963 data using a standardized roadside, single observer point count protocol and has been
964 collecting data regularly across North America (??) since 1966. The roadside surveys
965 consist of 50 point counts (by sight and sound) along an approximately 24.5 mile
966 stretch of road. Due to strict reliance on volunteers, some routes are not covered every
967 year. Additionally, some routes are moved or discontinued, and some routes are not
968 sampled in a given year. Route-year combinations which are missing years but are not
969 discontinued are treated as missing data. Although NABBS volunteers identify all
970 species as possible, persistent biases exist in this protocol. To reduce the influence of
971 potential sampling bias, I removed waterfowl, waders, and shore species (AOU species
972 codes 0000 through 2880).

973 **4.2.2 Study area**

974 Although the NABBS conducts surveys throughout much of North America, I limited
975 analyses to the continental United States and parts of southern Canada. NABBS
976 coverage of the boreal forests of Canada are sparse in space, and many routes in
977 Mexico have fewer than 25 years of observations.

978 **Focal military base**

979 The Mission of the US Department of Defense is to provide military forces to deter
980 war and protect the security of the country, and a primary objective of individual
981 military bases is to maintain military readiness. To maintain readiness, military
982 bases strictly monitor and manage their natural resources. Military bases vary in
983 size and nature, and are heterogeneously distributed across the continental United
984 States (See Fig. 4.1). The spread of these bases (Fig. 4.2), coupled with the top-
985 down management of base-level natural resources presumably influences the inherent
986 difficulties associated with collaborative management within and across military bases
987 and other natural resource management groups (e.g., state management agencies,

Figure 4.1: A single East-West transect of Breeding Bird Survey routes used to calculate the Fisher Information.

988 non-profit environmental groups.

989 Much like other actively managed landscapes, military bases are typically sur-
990 rounded by non- or improperly-managed lands. Natural resource managers of military
991 bases face environmental pressures within and surrounding their properties, yet their
992 primary objectives are very different. Natural resource managers of military bases,
993 whose primary objective is to maintain military readiness, are especially concerned
994 with if and how broad-scale external forcings might influence their lands. Prominent
995 concerns include invasive species, wildlife disease, and federally protected species
996 (personal communication with Department of Defense natural resource managers at

997 Eglin Air Force and Fort Riley military bases). For these reasons, natural resource
998 managers attempt to create buffers along their perimeters (e.g., live fire/ammunitions
999 suppression, wide fire breaks). Identifying the proximity of military bases to historic
1000 and modern ecological shifts may provide insight into the effectiveness of their natural
resource management efforts. The NABBS routes chosen for analyses in this Chapter

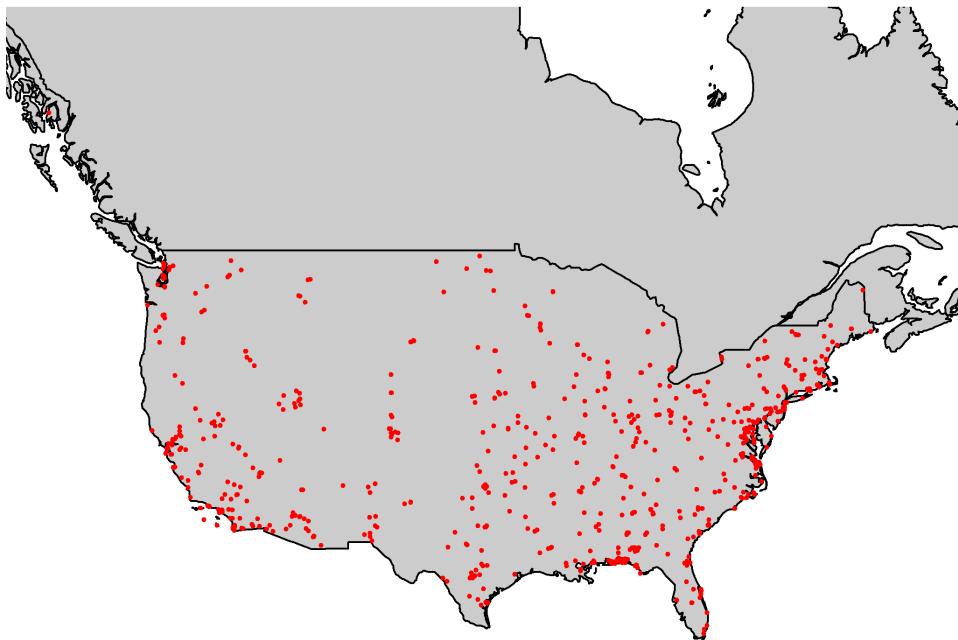

Figure 4.2: Locations of U.S. military bases in our study area.

1001
1002 lie within or near Fort Riley military base (located at approximately 39.110474° ,
1003 -96.809677° ; Kansas, USA). Fort Riley (Fig. 4.3) is a useful reference site for this
1004 study. Woody encroachment of the Central Great Plains over the last century has
1005 triggered shifts in dominant vegetative cover and diversity (Ratajczak et al. 2012) in
1006 the area surrounding Fort Riley military base (e.g., Van Auken 2009). This phenomena

1007 should present itself as a regime boundary should Fisher Information be a robust
regime shift detection method.

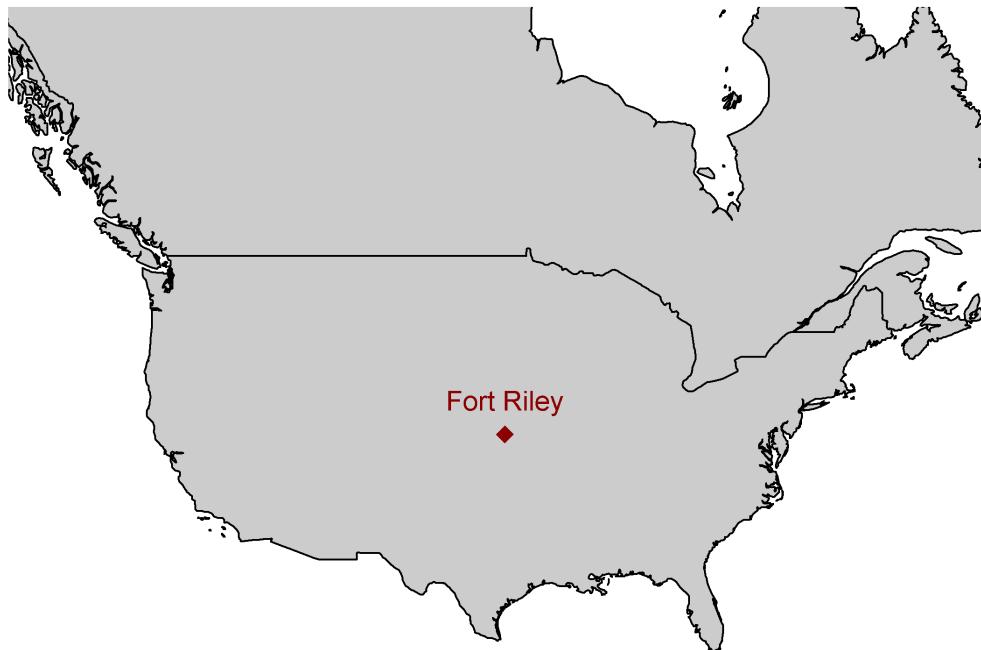

Figure 4.3: Locations of focal U.S. military bases, Eglin Air Force Base (AFB) and Fort Riley Military Base.

1008

1009 Spatial sampling grid

1010 To my knowledge, (???) is the only study to use the Fisher Information on spatially-
1011 referenced data. The authors of this study hand-picked NABBS routes to be included
1012 in their samples such that their metrics should detect ‘regime changes’ when adjacent
1013 sampling points represented different ecoregions (broad-scale vegetation classification
1014 system). The authors also suggest each ecoregion is similarly represented, having a

1015 similar number of NABBS routes within each ecoregion in the analysis. However, this
1016 method of handpicking routes resulted in a transect which was neither North-South
nor East-West running (see (??)), but rather zigzagged across a midwestern region. I

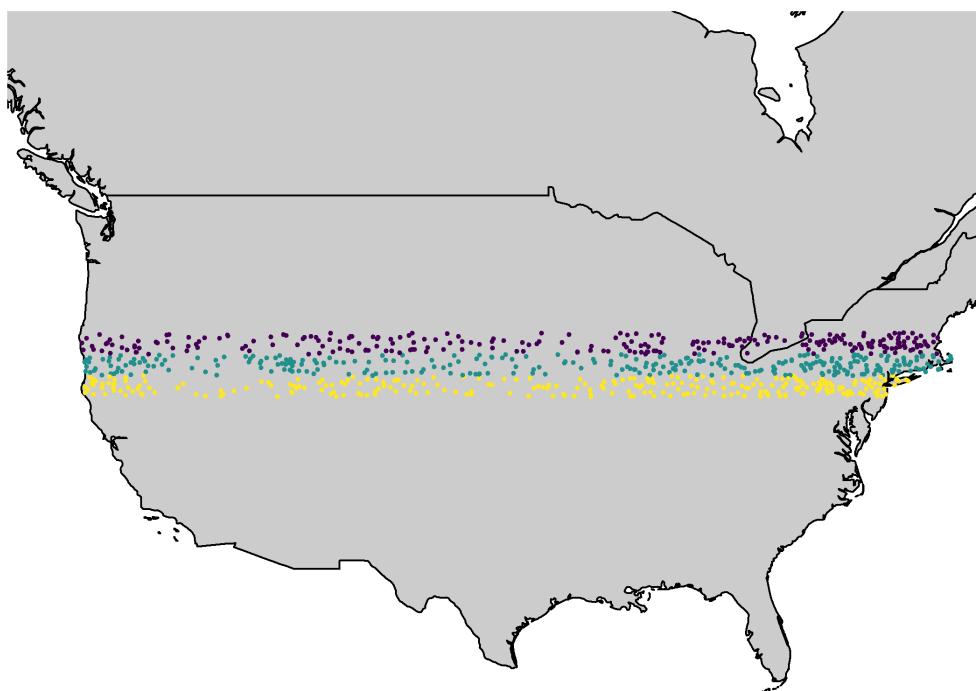

Figure 4.4: The three East-West running transects used to visualize results in this chapter.

1017
1018 constructed a gridded system across the continental United States and parts of Canada.
1019 The gridded system comprises East-West running transects running in either
1020 North-South or East-West directions. This method ameliorates some sampling bias, as
1021 I have arbitrarily defined sampling transects, rather than hand-picking sites to include
1022 in the analysis. Additionally, this approach allows for raster stacking, or layering data
1023 layers (e.g., vegetation, LIDAR, weather) on top of the sampling grid and results,

allowing one to identify potential relationships with large-scale drivers. This method also provides a simple vector for visualizing changes in the Fisher Information over space-time, using animations and still figures. For brevity, I present visual results of only three, spatially-adjacent, East-West running transects (Fig. 4.4) at multiple time periods.

4.2.3 Calculating Fisher Information (FI)

Fisher Information, $I(\theta)$, was developed in 1922 by Ronald Fisher as a measure of the amount of information that an observable variable, X, reveals about an unknown parameter, θ . Fisher Information is a measure of indeterminacy (Fisher 1922) and is defined as,

$$I(\theta) = \int \frac{dy}{p(y|\theta)} \left[\frac{dp(y|\theta)}{d\theta} \right]^2 \quad (4.1)$$

where $p(y|\theta)$ is the probability density of obtaining the data in presence of θ . The Fisher Information measure (FIM) is used to calculate the covariance matrix associated with the likelihood, $p(y|\theta)$. Fisher Information is described as Extreme Physical Information (EPI; Frieden and Soffer 1995, Kibble 1999, Frieden et al. 2002), a measure that has been used to track the complexity of systems in many scientific disciplines including, physics, cancer research, electrical engineering, and, recently, complex systems theory and ecology

Fisher Information as gathered from observational data provides insight as to the dynamic order of a system, where an orderly system is one with constant (i.e., unchanging) observation points, and one whose nature is highly predictable. A disorderly system is just the opposite, where each next data point is statistically unpredictable. In ecological systems, patterns are assumed to be a realization of ecosystem order; therefore, one should expect orderliness in a system with relatively stable processes and feedbacks. Orderliness, however, does not necessarily infer long-

1048 term predictability. Equation (4.1) is next adapted to estimate the dynamic order of
 1049 an entire system, s , as

$$I = \int \frac{ds}{p(s)} \left[\frac{dp(s)}{ds} \right]^2 \quad (4.2)$$

1050 where $p(s)$ is the probability density for s . Here, a relatively high Fisher Information
 1051 value (I) infers higher dynamic order, whereas a lower value (approaching zero) infers
 1052 less orderliness. To limit the potential values of I in real data, we can calculate the
 1053 amount of Fisher Information by re-expressing it in terms of a probability amplitude
 1054 function $q(s)$ (Fath et al. 2003, Mayer et al. 2007, eq. 7.3):

$$I = 4 \int ds \left[\frac{dq(s)}{ds} \right]^2 \quad (4.3)$$

1055 A form specific to the pdf of distance travelled by the entire system, which I call the
 1056 ‘derivatives’ method, is defined as (Mayer et al., 2007, eq. 7.12):

$$I = \frac{1}{T} \int_0^T dt \left[\frac{s''^2}{s'^4} \right]^2 \quad (4.4)$$

1057 where T is the number of equally spaced time points over which the data are integrated.
 1058 Numerical calculation of I using the binning method (Eq. (4.3) and (4.4)) each
 1059 incorporate a moving-window procedure for calculating the probability of the system,
 1060 $p(s)$, as being in one of an unidentified number of states (s). Although previously
 1061 applied to spatially-explicit terrestrial community data, the binning method (Eq. ??)
 1062 requires multiple parameters to be defined *a priori*, which have been shown to influence
 1063 inference based on the metric. I therefore calculated FI using the derivatives equation
 1064 (Eq. ??).

1065 The binning procedure allows for a single point in time or space to be categorized
 1066 into more than one state, which violating the properties of alternative stable states
 1067 theory. The size of states (see Eason and Cabezas 2012) measure is required to construct

1068 $p(s)$. In the case of high dimensional data, a univariate binning procedure of $p(s)$ is
1069 not intuitive (i.e., reducing a multivariable system to a single probability distribution
1070 rather than constructing a multivariate probability distribution). Importantly, when
1071 using community or abundance data, rare or highly abundant species can influence
1072 the size of states criterion, thus influencing the assignment of each point into states.
1073 Finally, Eq. (4.3) assumes equal spacing (in space or time) between sampling points.
1074 Each of these violations can be avoided by using Eq. (4.4); Cabezas and Fath 2002,
1075 Fath et al. 2003) to calculate the Fisher Information measure. The derivatives method
1076 (Eq. (4.4)) estimates the trajectory of the system's state by calculating the integral of
1077 the ratio of the system's acceleration and speed in state space (Fath et al., 2003). I
1078 calculated Fisher Information using Equation (4.4) for all East-West transect (see Fig.
1079 ??) for years 1980, 1990, 2000, and 2010.

1080 **4.2.4 Interpreting and comparing Fisher Information across
1081 spatial transects**

1082 **Interpreting Fisher Information values**

1083 Here I define a potential regime change as a point(s) having a non-zero derivative, and
1084 at which relatively large changes (sharp increase or decrease) in the Fisher Information
1085 measure occur. Regime shifts are identified as data changing from one state to another,
1086 thus, rapid shifts in the value of FI should indicate the points, in time or space, at
1087 which the system undergoes reorganization. Spatial and temporal Fisher Information
1088 calculation does not vary, but interpretation of either differ in that a spatial analysis
1089 will identify a spatial regime boundary (???) in space within a single time period,
1090 whereas analysis of temporal data will identify a point(s) in time at which a system
1091 in a specific location undergoes a regime shift. I follow the methods outlined in the
1092 relevant literature for interpreting the Fisher Information (e.g., Karunanithi et al.,

1093 2008, p. @eason_evaluating_2012).

1094 Increases in FI is proposed as an indicator of system orderliness, where periods of
1095 relatively high values of FI indicate the system is in an “orderly” state, or is fluctuating
1096 around a single attractor. A rapid change in FI is supposed to indicated the system
1097 is no longer orderly and may be undergoing a reorganization phase. Whether Fisher
1098 Information can identify a switch among basins of attraction within a single, stable
1099 state (or around a single attractor) remains unknown, as does the number of states
1100 which a system can occupy. When a system occurs within any number of states
1101 equally, i.e., $p(s)$ is equal for each state, both the derivative, $(\frac{dq(s)}{ds})$, and I are zero. As
1102 $(\frac{dq(s)}{ds} \rightarrow \infty)$, we infer the system is approaching a stable state, and as $\frac{dq(s)}{ds} \rightarrow 0$ the
1103 system is showing no preference for a single stable state and is on an unpredictable
1104 trajectory. (4.3) bounds the potential values of Fisher Information at $[0, 8]$, whereas
1105 (4.1), (3.4), and (4.4) have are positively unbounded $[0, \infty)$. If the Fisher Information
1106 is assumed to represent the probability of the system being observed in some state,
1107 s , then the absolute value of the Fisher Information index is relative within a single
1108 datum (here, transect). It follows that Fisher Information should be interpreted
1109 relatively, but not absolutely.

1110 **Interpolating results across spatial transects**

1111 Because the BBS routes are not regularly spaced, pairwise correlations of adjacent
1112 transects are not possible without either binning the Fisher Information calculations
1113 using a moving-window analysis, or interpolating the results to regularly-spaced
1114 positions in space. To avoid potential biases associated with the former option, I
1115 linearly interpolated Fisher Information within each spatial transect (Fig. 4.4) at 50
1116 points along the longitudinal axis. The 50 longitudinal points at which I interpolated
1117 were the same across each spatial transect. I used the function *stats::approx()* to
1118 linearly approximate the Fisher Information. I did not interpolate values beyond the

longitudinal range of the original data (using argument `rule=1` in package `approx`).

Figure 4.5: An example of two adjacent spatial transects within my sampling grid.

1119

1120 **Spatial correlation of Fisher Information**

1121 If Fisher Information captures and reduces information regarding abrupt changes in
1122 community structure across the landscape, then the values of FI should be spatially
1123 autocorrelated. That is, the correlation of FI values should increase as the distance
1124 between points decreases. Fisher Information values calculated using Eq. (4.4) are
1125 **not** relatively comparable outside of our spatial transects, because the possible values
1126 are unbounded (can take on any value between $-\infty$ and ∞ . However, because FI is

Figure 4.6: An example of two adjacent spatial transects (12, 13) within my sampling grid.

1127 directly comparable **within** each spatial transect (e.g., 4.5), we can use pairwise
1128 correlations among two transects (e.g., 4.5) to determine whether values of FI are
1129 consistent across space. I calculate the pairwise correlation (Pearson's) among each
1130 pair of adjacent spatial transects (e.g., Fig. 4.6). I removed a pair of points if at least
1131 one point was missing an estimate for Fisher Information. This occurred when the
1132 original longitudinal range of one transect exceeded its pair's range, since I did not
1133 interpolate beyond the original longitudinal range.

¹¹³⁴ **4.3 Results**

¹¹³⁵ **4.3.1 Fisher Information across spatial transects**

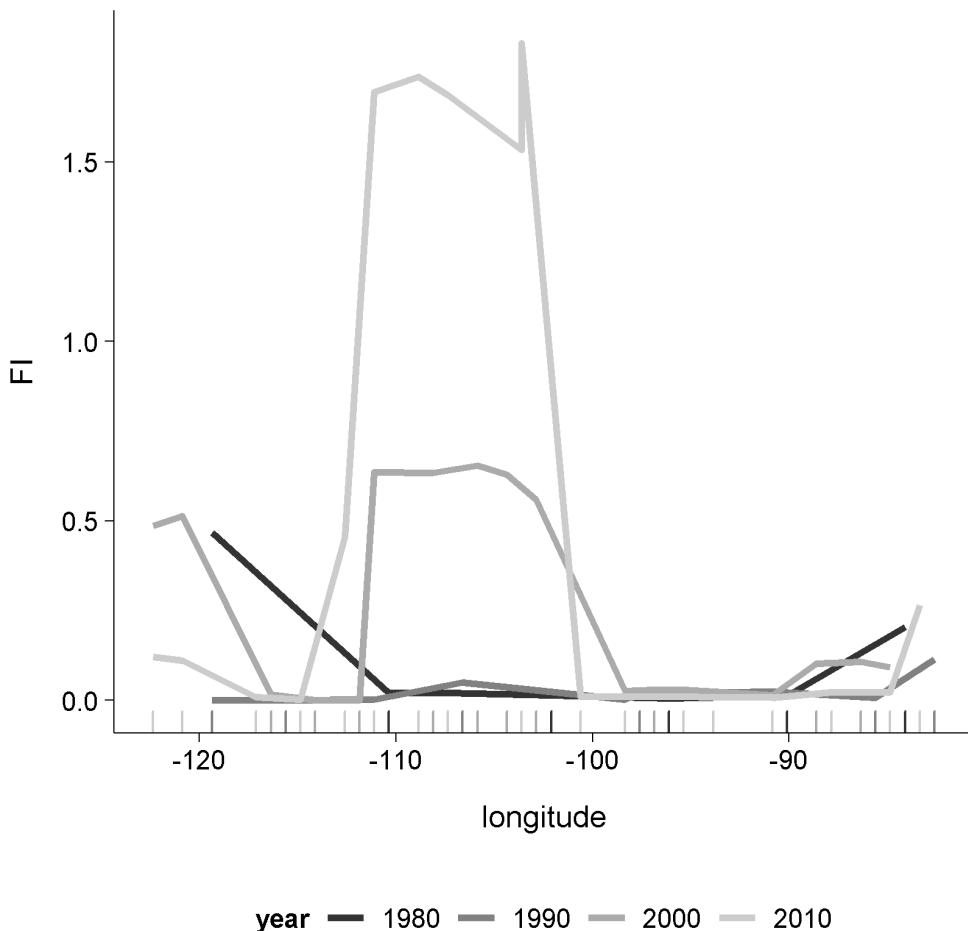

Figure 4.7: Fisher Information calculated for a single transect over time.

¹¹³⁶ Interpreting the Fisher Information is currently a qualitative effort. As suggested
¹¹³⁷ earlier, rapid increases or decreases in FI are posited indicate a change in system
¹¹³⁸ orderliness, potentially suggesting the location of a regime shift. Using this method
¹¹³⁹ yields inconclusive results regarding the location of ‘spatial regimes’ (Fig. 4.7). Of the
¹¹⁴⁰ three spatial transects analyzed in this chapter (Fig. 4.4), Fig. 4.7 is representative
¹¹⁴¹ of the lack of pattern observed in the Fisher Information values across transects. I
¹¹⁴² identified no clear pattern within or among spatial transects. Log-transforming the

1143 Fisher Information metric suppresses some of the extreme values, but still does not
1144 clearly identify sharp changes in the Fisher Information values.

1145 **4.3.2 Spatial correlation of Fisher Information**

1146 In addition to failing to identfify clear geological boundaries across large swaths of our
1147 study area, (Fig ??) I also did not identify spatial correlation of Fisher Information
1148 among adjacent spatial transects (Fig. 4.8)¹. For spatially-adjacent transects (e.g.,
1149 transects 11 and 12, or 12 and 13 in Fig. 4.8), we should expect high and positive
1150 correlation values, and these values shoudl stay consistent across time *unless* the spatial
1151 transects were separated by an East-West running physical or functional boundary.
1152 This is not, however, what I expect in our East-West running transects (Fig. ??),
1153 as the spatial soft-boundaries limiting the distribution and functional potential of
1154 avian communities are largely North-South (Fig. @ref(ewRoutes_ecoRegions)). Note
1155 spatial transects in Fig. @ref(fig:ewRoutes_ecoRegions) overlap multiple, large spatial
1156 ecoregion boundaries, such that we should expect our data to identify these points
1157 (boundaries). Upon initial investigation, there are no obvious signs of broad-scale
1158 patterns in FI across space (Fig. 4.10)². If Fisher Information is an indicator of
1159 spatial regime boundaries, we should expect to see large changes in its value (in either
1160 direction) near the edges of functional spatial boundaries (e.g., at the boundaries
1161 of ecoregions). No clear regime changes appeared in areas where we might expect
1162 rapid changes (e.g., along the 105th meridian West, where a sharp change in altitude
1163 occurs).

1164 Numerical investigation of the spatial correlation among adjacent transects also
1165 yielded no clear patterns. I did not identify any obvious correlation with changes in

¹Pairs were compared (column) at select sampling years (rows), and pair-wise correlations among paired transects are presented. Large, positive correlations indicate Fisher Information signals similarly at adjacent spatial transects.

²Size indicates value of Fisher Information (values are scaled and centered within transects). Red box (in top panel) indicates extent of bottom panel.

₁₁₆₆ FI values and functional potential (using Omernick Ecoregion Level 2; see Fig. 4.10).
₁₁₆₇ Rather than abrupt changes in Fisher Information I found gradual changes (e.g., see
₁₁₆₈ results for years 2000 and 2010 in Figs. 4.11,4.10).

₁₁₆₉ 4.4 Discussion

₁₁₇₀ The Fisher Information measure was introduced as a method to avoid some analytical
₁₁₇₁ issues related to complex and noisy ecological data (Karunanithi et al., 2008), and
₁₁₇₂ has also been suggested as an indicator of *spatial* regimes (???). I found no evidence
₁₁₇₃ suggesting Fisher Information [Eq. (4.4)] can identify ‘spatial regimes’. Further,
₁₁₇₄ the absence of autocorrelation among spatially adjacent transects suggests Fisher
₁₁₇₅ Information may not be a reliable indicator of changes in bird community structure.

₁₁₇₆ Although the Fisher Information equation [Eq. (4.4)] used in this study is a
₁₁₇₇ relatively straightforward and fairly inexpensive computational calculation, extreme
₁₁₇₈ care should be taken when applying this index to ecological data. Fisher Information
₁₁₇₉ is capable of handling an infinite number of inputs (variables), and given sufficiently

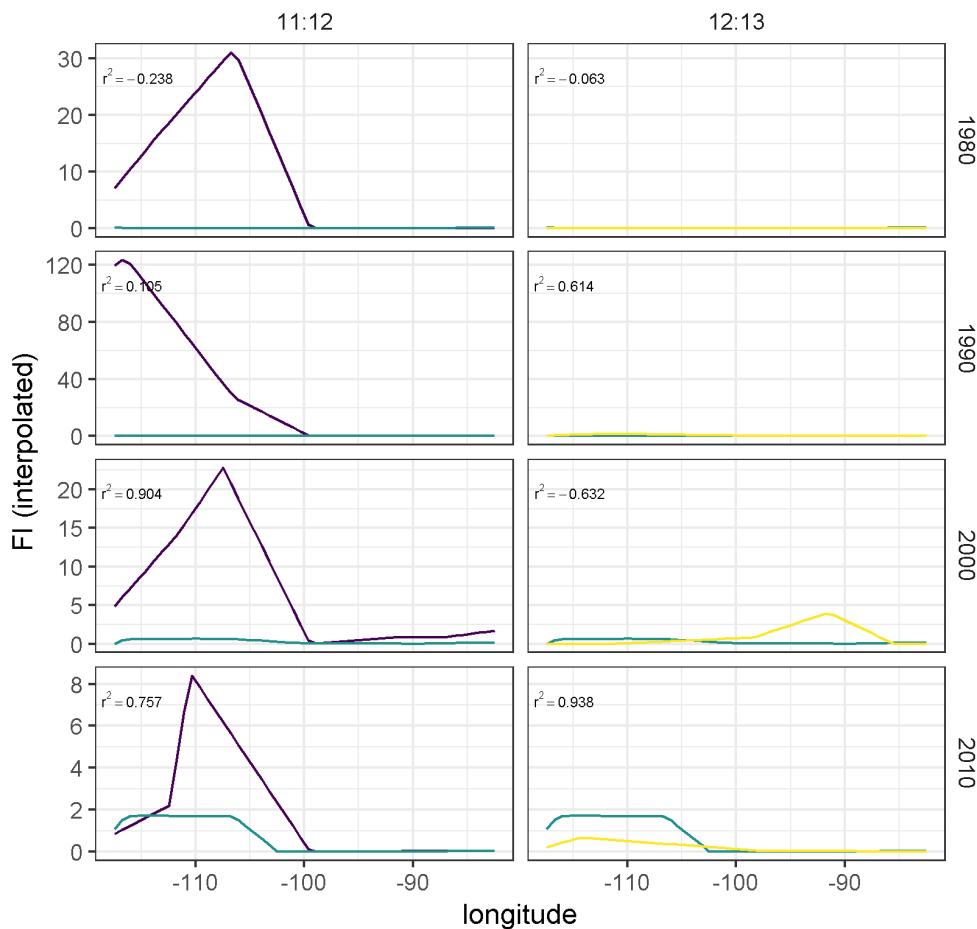

Figure 4.8: Pairwise relationships of Fisher Information (interpolated values) of spatially adjacent transects over time.

1180 low window size paramters, can technically calculate an index value for only two
 1181 observations. It is important that the user understands the assumptions of identifying
 1182 'regime shifts; using Fisher Information, since the efficacy of this method has not
 1183 been yet subjected to rigorous tests (but see 6). There are three primary assumptions
 1184 required when using Fisher Information to estimate relative orderliness within ecological
 1185 data (Mayer et al., 2007):

- 1186 1. the order or state(s) (s) of the system is observable, 1. any observable change in
 1187 the information observed in the data represents reality and the variables used in the
 1188 analyses will not produce false negatives, and 1. changes in I presumed to be regime
 1189 shifts do not represent the peaks of cyclic (periodic) patterns.

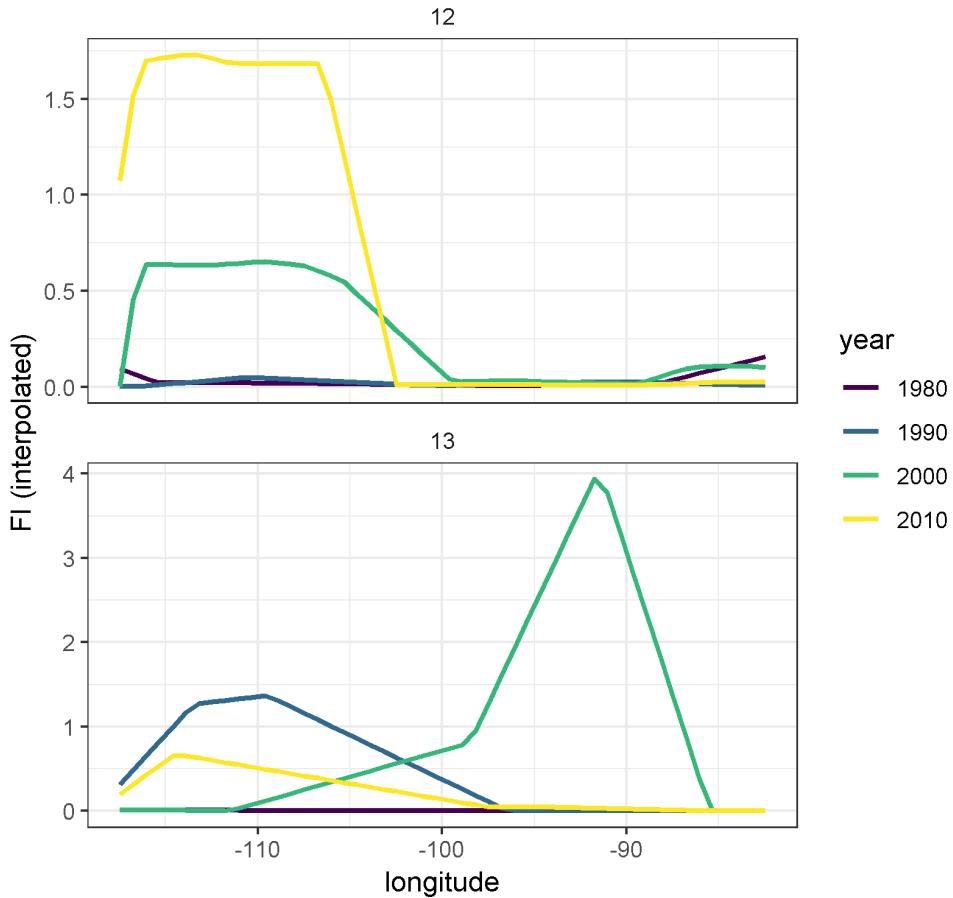

Figure 4.9: Fisher Information of two transect pairs over time.

1190 The first assumption is one of philosophical debate and is thus not controllable. To
 1191 attempt to control for false negatives, the user should take caution in her choice of input
 1192 variables. In the the case of a high dimensional data, relativization and/or variable
 1193 reduction measures may be useful (Rodionov 2005). However, Fisher Information
 1194 does not convey information on how specific variables relate to the calculated index.
 1195 Finally, we can take measures to account for cyclic behavior in the data by ensuring
 1196 integration periods capture at one full cycle of the system and, given sufficiently high
 1197 number of observations, increasing the integration period may also alleviate some
 1198 issues related to irreducible error (white noise).

1199 The lack of patterns identified using Fisher Information may be influenced by one or
 1200 more of the following: (1) the Breeding Bird Survey data collection scheme was designed

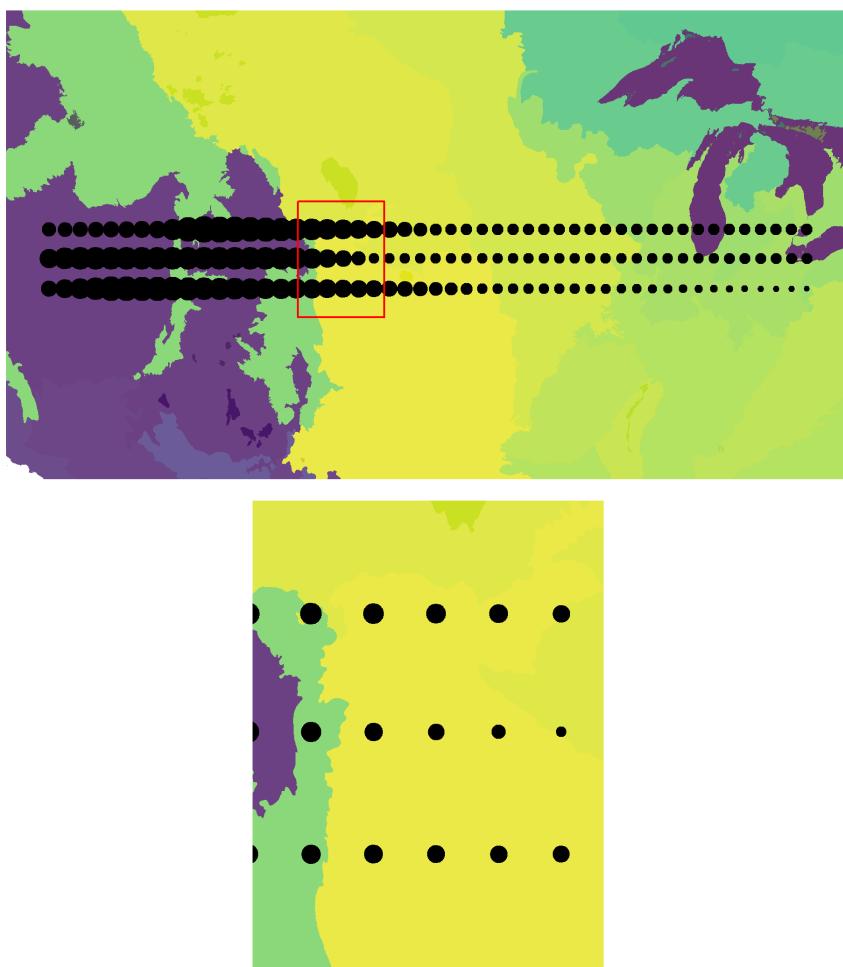

Figure 4.10: No patterns of abrupt change detected in Fisher Information along three transects in year 2010

1201 to estimate and track **species** trends and not changes in entire communities; (2) these
1202 data consist of < 50 time points, and for some BBS routes much fewer. Ecological
1203 processes affecting large regions in this study area (e.g., the Central Great Plains)
1204 operate on larger time scales (i.e., » 50 points). A mismatch among the ecologically
1205 relevant scales and the temporal resolution and extent of our data may influence the
1206 ability of this index to capture large-scale changes in whole bird communities.

1207 Aside from the typical biases associated with the BBS data (e.g., species detection
1208 probability, observer bias), there are additional considerations to be made when using
1209 these data to identify ‘spatial regimes’. Breeding Bird Survey routes are spaced apart

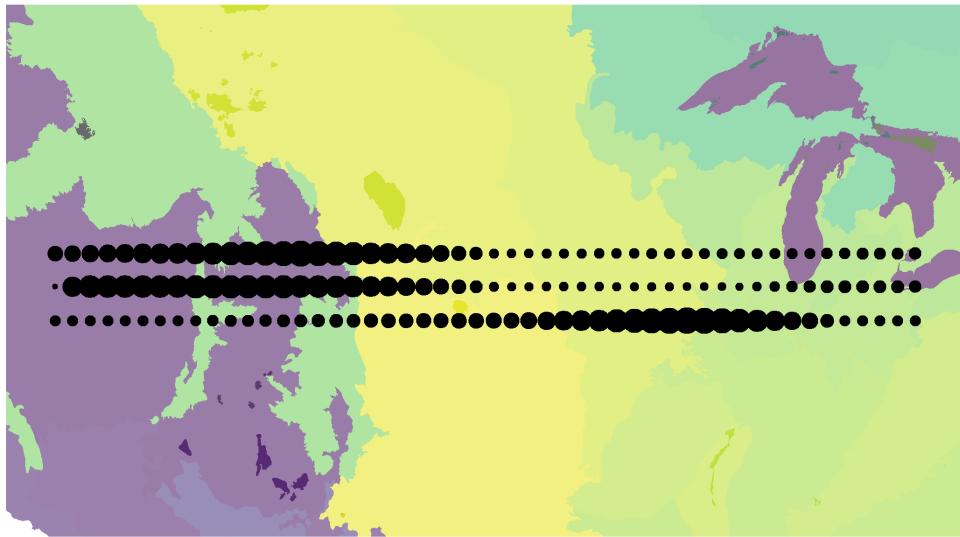

Figure 4.11: Fisher Information (scaled and centered; point size positively correlated with value) against ecoregion boundaries (EPA Level 2).

so as to reduce the probability of observing the same individuals, but birds which fly (especially in large flocks) overhead to foraging or roosting sites have a higher probability of being detected on multiple routes. We have, however, removed these species (waders, shorebirds, waterfowl, herons) from analysis. Regardless, this study assumes there is potential for each unique BBS route to represent its own state. If routes were closer together, it is more probable that the same type and number of species would be identified on adjacent routes. Therefore, if this method does not detect slight changes in nearby routes which occupy the same ‘regime’, then it follows that the method is sensitive to loss or inclusion of new species, which are spatially

1219 bounded by geological and vegetative characteristics. What new information does this
1220 give us about the system? Fisher Information reduces and removes the dimensionality
1221 of these middle-numbered systems, which omits critical information.

1222 Effective regime detection measures should provide sufficient evidence of the
1223 drivers and/or pressures associated with the identified regime shifts (Mac Nally et al.,
1224 2014). The Fisher Information index collapses a wealth of data into a single metric,
1225 thereby foregoing the ability to relate state variables to the observed changes in Fisher
1226 Information, unlike other dimension reduction techniques. For example, loadings, or
1227 the relative influence of variables on the ordinated axes, can be derived from a Principal
1228 Components Analysis—this cannot be achieved using Fisher Information. If Fisher
1229 Information clearly suggested a spatial regime boundary or shift, a before-and-after
1230 post-hoc analysis of the regional community dynamics might confirm the regime shift
1231 occurrence.

1232 4.4.1 Efficacy of Fisher Information as a spatial RDM

1233 This study found no evidence suggesting Fisher Information accurately and consistently
1234 detects spatial boundaries of avian communities. Rapid changes in either direction
1235 of Fisher Information is suggested to indicate of a regime shift (Mayer, Pawlowski,
1236 & Cabezas, 2006, @eason_evaluating_ 2012). Although this interpretation has
1237 been applied to multiple case studies of Fisher Information, there is yet a statistical
1238 indicator to objectively identify these abrupt changes. After calculating the Fisher
1239 Information for each spatial transect (Fig. 4.4) during each sampling year, I used
1240 pairwise correlation to determine whether spatial autocorrelation existed among pairs
1241 of spatial transects. If some set of points are close in space and are *not* separated by
1242 some physical or functional boundary (e.g., an ecotone, high altitude rock formations),
1243 then the Fisher Infomration calculate should exhibit a relatively high degree of spatial
1244 autocorrelation that is consistent over time. It follows that the correlation coefficient of

1245 spatially adjacent transects should be similar, diverging only as the distance between
1246 the transects differs and/or a functional or physical boundary separates them.

1247 Several questions remain regarding the efficacy of Fisher Information as a regime
1248 detection measure in both spatial and temporal data. If signals of regime shifts do
1249 exist, it is clearly not possible to identify them using visual interpretation. I also
1250 did not find evidence to suggest spatial autocorrelation of the calculations. I suggest
1251 future studies of Fisher Infomration focuses on temporal, rather than spatial data.

1252 Potential areas of research and questions include:

1253 1. Relationship of Fisher Information to likelihood ratio-based unsupervised
1254 change-point detection algorithms (e.g., ChangeFinder (Liu, Yamada, Collier, &
1255 Sugiyama, 2013)).

1256

1257 2. Sensitivity of Fisher Information to data quality and quantity [this is explored
1258 in Chapter 6].

1259

1260 3. What, if any, advantages does FI have over other density estimation techniques?

1261

1262 4. Does FI provide signals in addition to or different than geophysical and vegetative
1263 (e.g. LIDAR) observations (data)?

₁₂₆₄ **Chapter 5**

₁₂₆₅ **Velocity (v): using rate-of-change**

₁₂₆₆ **of a system's trajectory to identify**

₁₂₆₇ **abrupt changes**

₁₂₆₈ **5.1 Introduction**

₁₂₆₉ In this Chapter I describe the steps for calculating a ‘new’ metric, **system velocity**,

₁₂₇₀ for reducing the dimensionality and identifying abrupt shifts in high dimensional data.

₁₂₇₁ Although this is the first instance of this calculation to, alone, be suggested as a

₁₂₇₂ regime detection metric, it has been used as part of a larger series of calculations of

₁₂₇₃ the Fisher Information metric [see 3], first introduced in Fath et al. (2003). Below, I

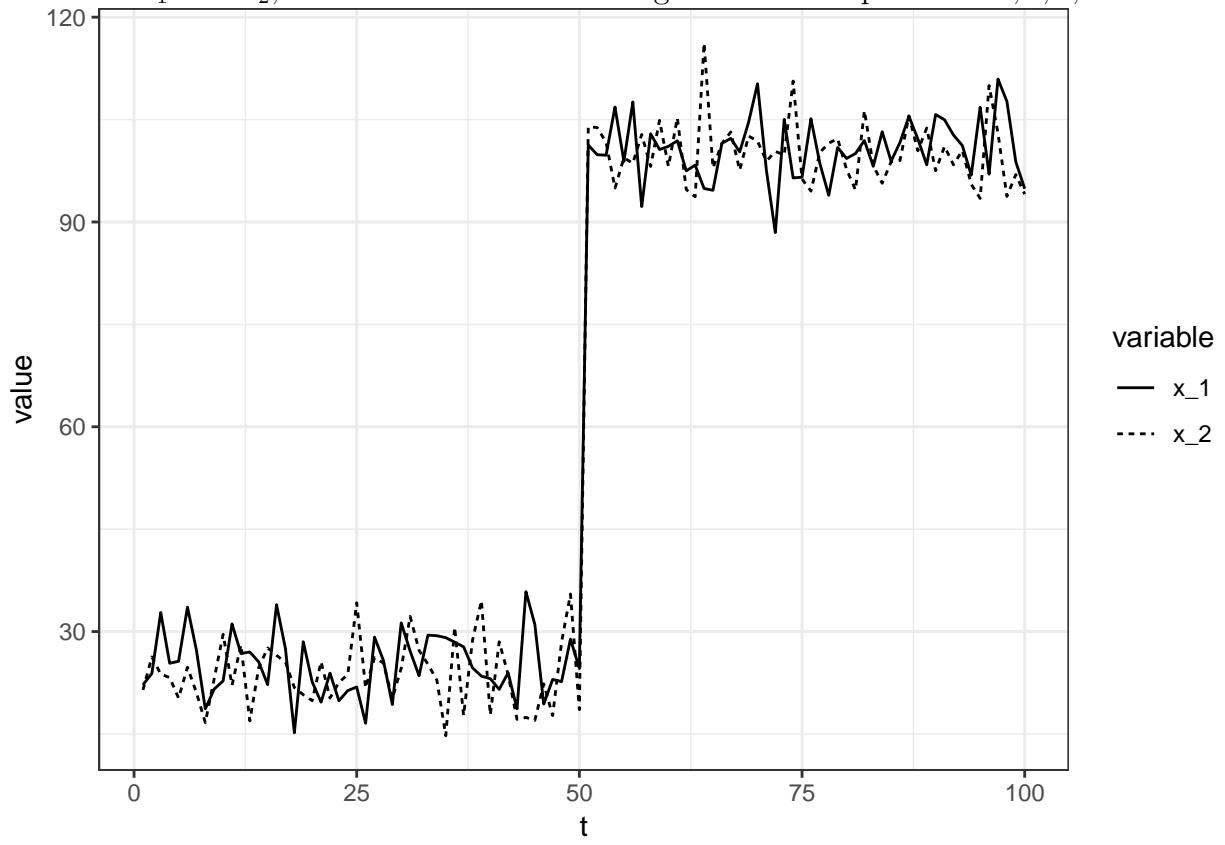

₁₂₇₄ describe the steps for calculating system velocity, simply defined as the cumulative

₁₂₇₅ sum of the squared change in all state variables over a period of time.

¹²⁷⁶ **5.2 Data and Methods**

¹²⁷⁷ **5.2.1 Theoretical system example: two-species time series**

¹²⁷⁸ Consider a system (Fig. ??) with N state variables (x_i), with observations taken
¹²⁷⁹ at time points, t . System velocity is calculated as the cumulative sum over time
¹²⁸⁰ period t_0 to t_j , as the total change in all state variables, $\{x_1 \dots x_N\}$, between two
¹²⁸¹ adjacent time points, e.g., t_j and t_{j+1} , denoted $t_{j,j+1}$. I use a simple, two-variable
¹²⁸² system to demonstrate the calculation of each step below. The system comprises
¹²⁸³ variables x_1 and x_2 , with observations occurring at each time point $t = 1, 2, 3, \dots, 100$.

¹²⁸⁴

¹²⁸⁵ **5.2.2 Steps for calculating system velocity, v**

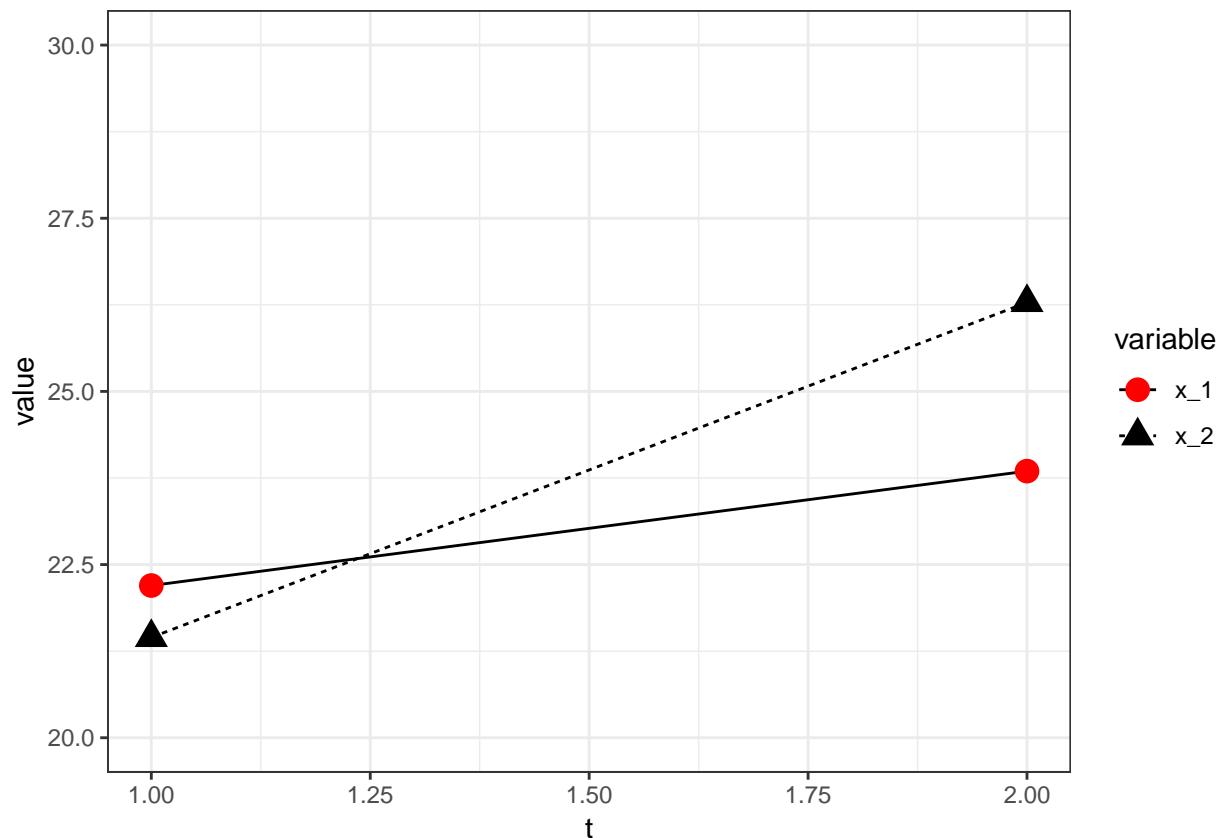

¹²⁸⁶ First, we calculate the change in each state variable, x_i , between two adjacent points
¹²⁸⁷ in time, t_j and t_{j+1} , such that the difference, $x_{t_{j+1}} - x_{t_j}$ is assigned to the latter time
¹²⁸⁸ point, t_{j+1} . For example, in our toy data, we use observations at time points $t = 1$ &

1289 $t = 2$ (Fig. ??). For all examples in this chapter, the state variables x_1 and x_2 were
1290 drawn from a normal distribution (using function *rnorm*), with parameters \bar{x}_i (mean)
1291 and σ_i (sd) for 100 time steps, t . The regime shift occurs at $t = 50$, where a shift in
1292 either or both \bar{x}_i or σ_i .

1293 **Step 1: Calculate Δx_i**

1294 The first step in calculating v is to obtain the change in values for each state variables,
1295 x_1 and x_2 between two consecutive time points (e.g., from $t = 1$ to $t = 2$:

$$\begin{aligned}\Delta x_1 &= x_{1t=2} - x_{1t=1} \\ \Delta x_2 &= x_{2t=2} - x_{1t=1}\end{aligned}\tag{5.1}$$

1297 **Step 2: Calculate** $\sqrt{(\sum_i^N \Delta x_1^2)}$

1298 After calculating the differences for each state variable, we will next calculate the total
 1299 change in the system over the time elapsed, following Pythagora's theorem,

$$X_1^2 + X_2^2 = s^2 \quad (5.2)$$

1300 where s represents the total change in the system, and X_1 and X_2 represent the
 1301 changes in all state variables ($x_{1t=2} - x_{1t=1}$). We achieve this by first squaring the
 1302 differences obtained in Eq. (5.1):

$$\begin{aligned} & (x_{1t=2} - x_{1t=1})^2 \\ & (x_{2t=2} - x_{2t=1})^2 \end{aligned} \quad (5.3)$$

1303

1304 **Step 3: Use Pythagorean theorem to isolate s**

1305 Next, we isolate s in Eq. (5.2), capturing the total change in all state variables into a
 1306 single measure by taking the 2nd root of the squared sums of all x :

$$\begin{aligned} \sum_{i=1}^N \Delta x_i &= \sum_{i=1}^N (x_{ti+1} - x_{ti})^2 \\ &= \Delta s \\ &= \sqrt{([x_{1t=2} - x_{1t=1}]^2 + [x_{2t=2} - x_{2t=1}]^2)} \end{aligned} \quad (5.4)$$

1307 We now have a single measure, Δs (Eq. (5.4)), for each pair of time points in our
 1308 N -dimensional system. It is obvious that Δs will always be a positive value, since
 1309 we took the 2nd root of a squared value. Although discussed in a later section, it is
 1310 important to note that this value is not unitless—that is, our example system takes on
 1311 the units of our state variables, x_1 and x_2 . Because we are interested in identifying
 1312 abrupt changes in the entire system, we calculate the cumulative sum of Δs at every

¹³¹³ time point, such that:

$$s = \sum_{t=1}^T \Delta s \quad (5.5)$$

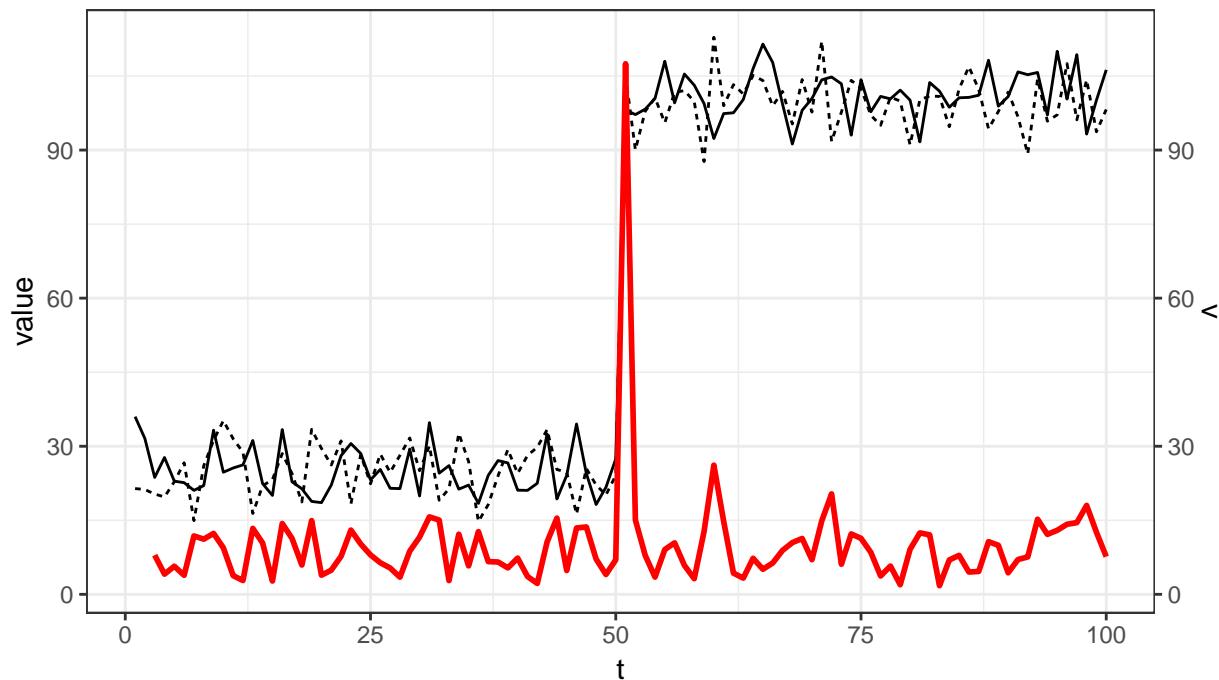

¹³¹⁴ ##### Step 4: Calculate velocity, v (or $\frac{\Delta s}{\Delta t}$) Finally, we calculate the **system velocity**,

¹³¹⁵ v (or $\frac{\Delta s}{\Delta t}$), by first calculating the change in s (Eq. (5.5)), and then divide by the total

¹³¹⁶ time elapsed between consecutive sampling points:

$$v = \frac{s_{t+1} - s_t}{\Delta t} \quad (5.6)$$

changing means, constant variance

¹³¹⁷

variable — x_1 ··· x_2

¹³¹⁸ The steps for calculating velocity [Eq. (5.6)] are demonstrated using the first five

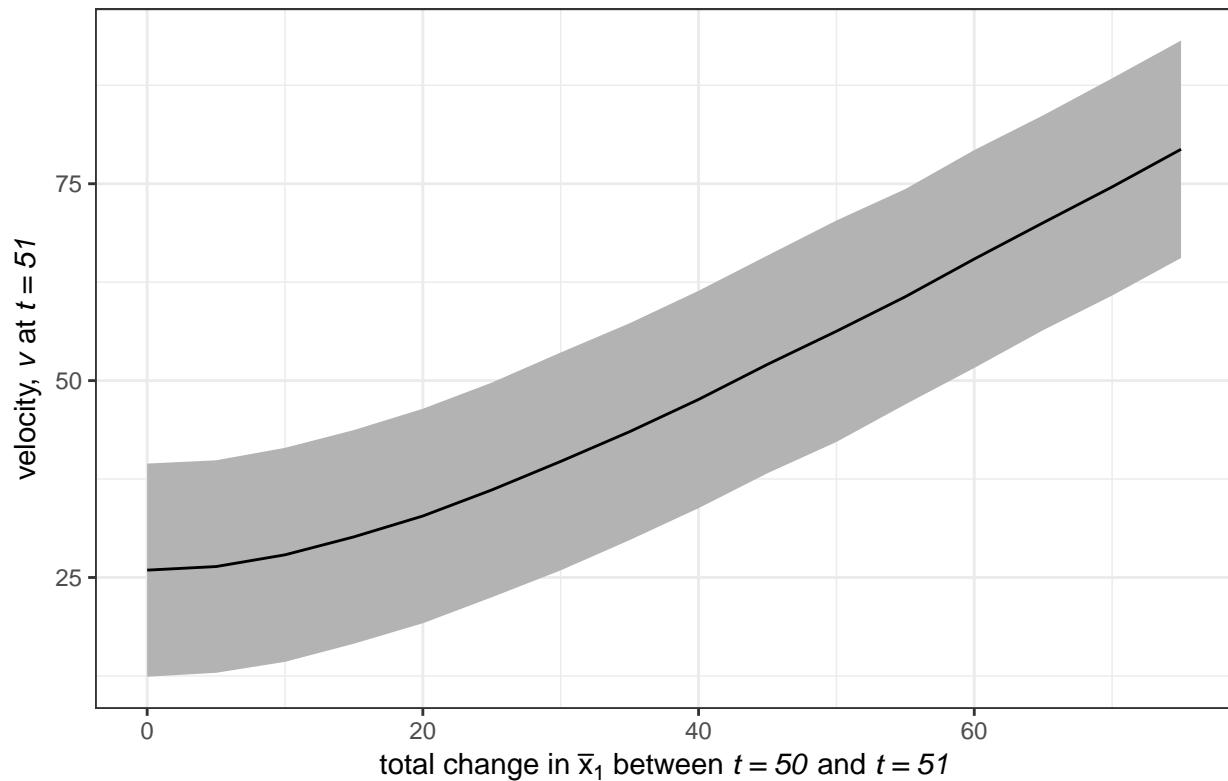

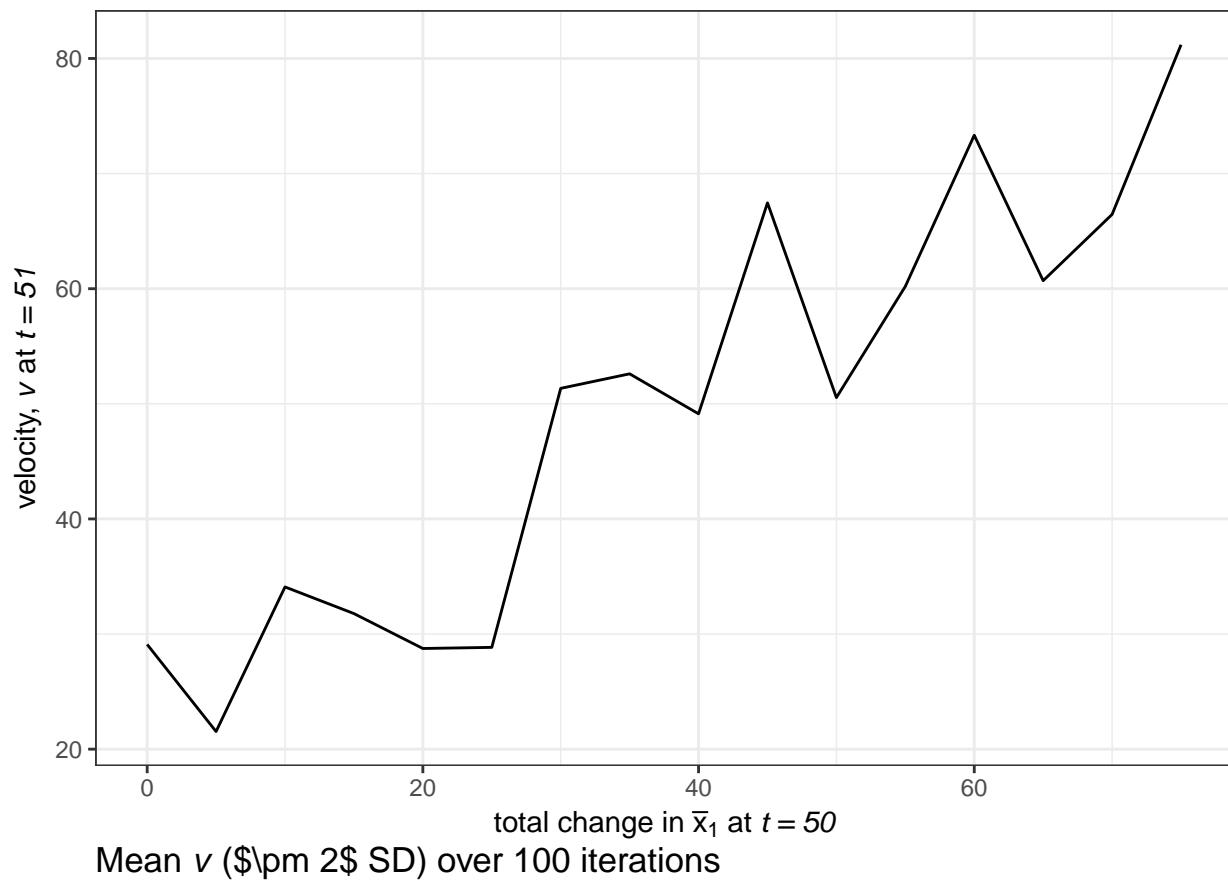

¹³¹⁹ time points of our toy system (Fig. ??) in Table ??.

1320 **5.2.3 Velocity v performance under varying mean and vari-
1321 ance in the toy system**

1322 I simulated 10,000 random draws of the toy system, which experiences a rapid shift at
1323 $t = 50$, while varying two each of the following system parameters at the regime shift:
1324 \bar{x}_1 , increased the mean value of x_1 σ_1 , change in variance of x_1 . Simulations consisted
1325 of 10,000 random samples drawn from the normal distribution for each parameter, I
1326 randomly drew the toy system samples 10,000 times under increasing values of \bar{x}_1
1327 and σ_1 . To identify patterns in the influence of parameter values on velocity, I present
1328 the mean values of v across all simulations, with confidence intervals of ± 2 standard
1329 deviations. As mentioned above, the state variables x_1 and x_2 were drawn from a
1330 normal distribution (using function *rnorm*), with parameters \bar{x}_i (mean) and σ_i (sd)
1331 for 50 time steps, t .

1332 **Varying post-shift mean**

1333 I examined the influence of the magnitude of change in x_1 in the period before
1334 (pre; $t < 50$) and after (post; $t \geq 50$) by varying the mean parameter, \bar{x}_1 in
1335 the set $W = \{25, 30, 35, \dots, 100\}$ (Figs. ??, ??). As expected, the magnitude of
1336 v increased linearly as the total difference between $\bar{x}_{1,pre}$ and $\bar{x}_{1,post}$ increased
1337 (??). This is not surprising, as s increases as the total change in abundance
1338 across the entire system increases (Eq. (5.5)), therefore, the potential maximum
1339 of v also increases. This may indicate that v , while capable of identifying large
1340 shifts in data structure, may not pick up subtle changes (i.e. lower effect sizes).

1343 Varying post-shift variance

1344 In the previous example, variance was constant before and after the shift at $t = 50$. To
 1345 determine whether the signal emitted by v at the regime shift is lost with increasing
 1346 variance, I varied the variance parameter, σ_1 in the set $W = \{1, 2, 3, \dots, 25\}$. The
 1347 variance for both state variables prior to the regime shift, σ_1 and σ_2 , was 5, with
 1348 the change occurring in σ_{1post} . System velocity v appears sensitive to increases in the
 1349 variance at the point of the regime shift (Figs. ??, ??). This extreme sensitivity
 1350 of v to σ_{post} (Fig. ??) is unsurprising, given the fact that, without smoothing the
 1351 derivatives, the tangential speed of a ‘noisy’ variable will always be noisy itself (see
 Figs. ??, ??, ??, ??).

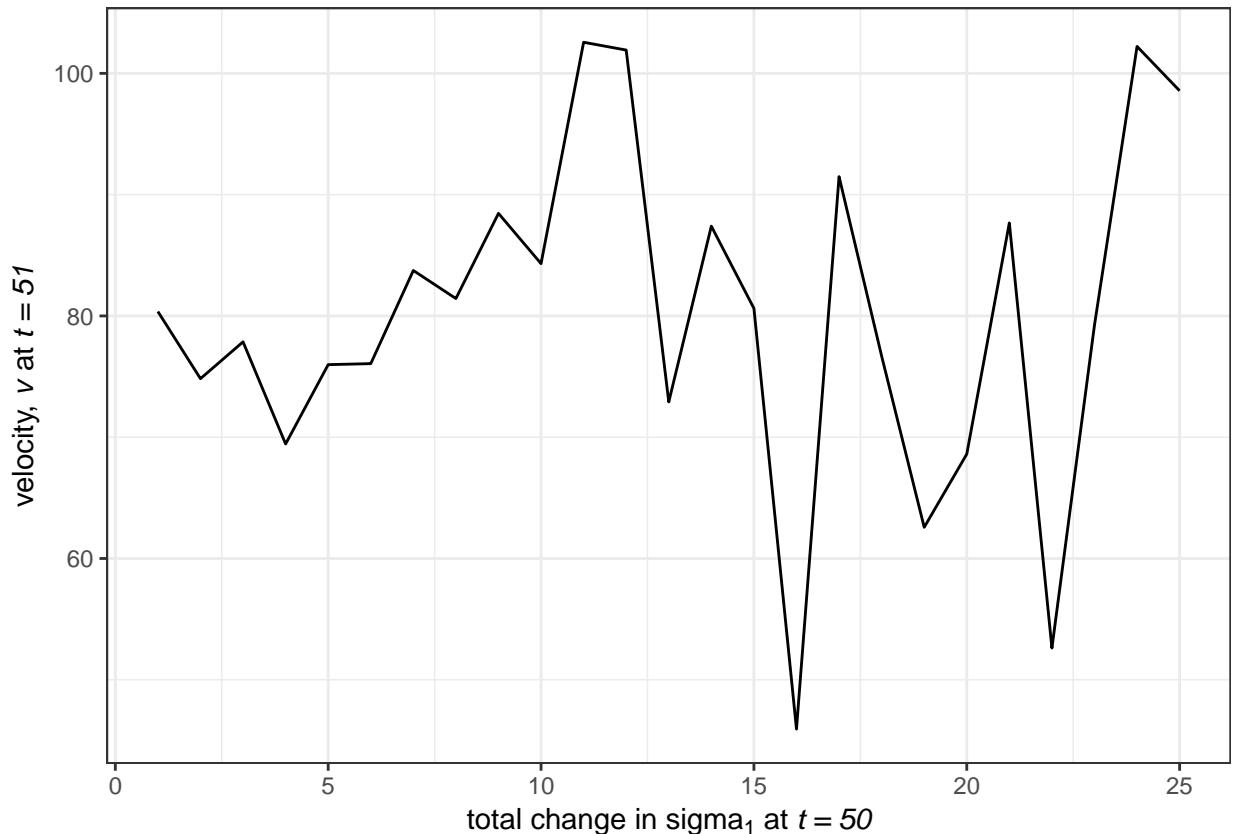

Figure 5.1: High variance of velocity (v) in a single iteration ($N_{iter} = 1$, seed = 123) of simulations as we increase σ_1 at $t = 50$.

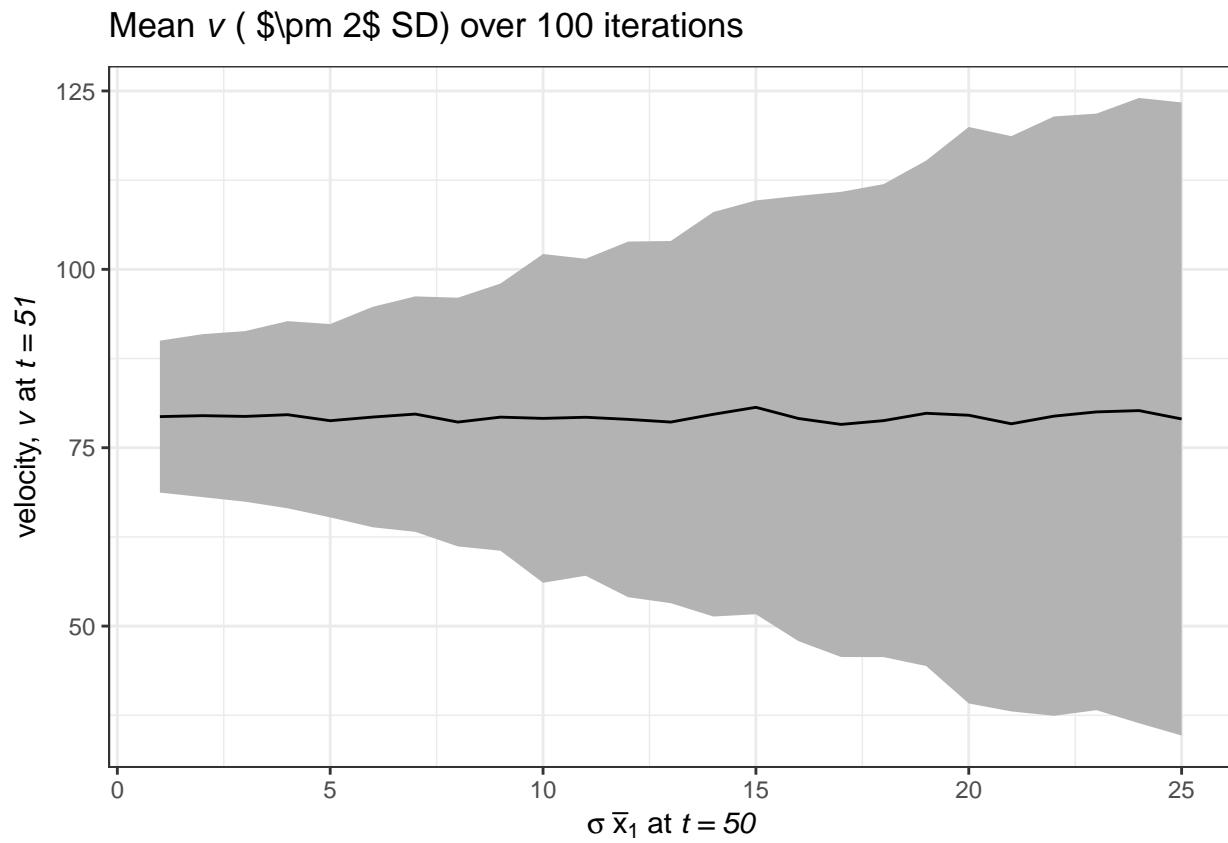

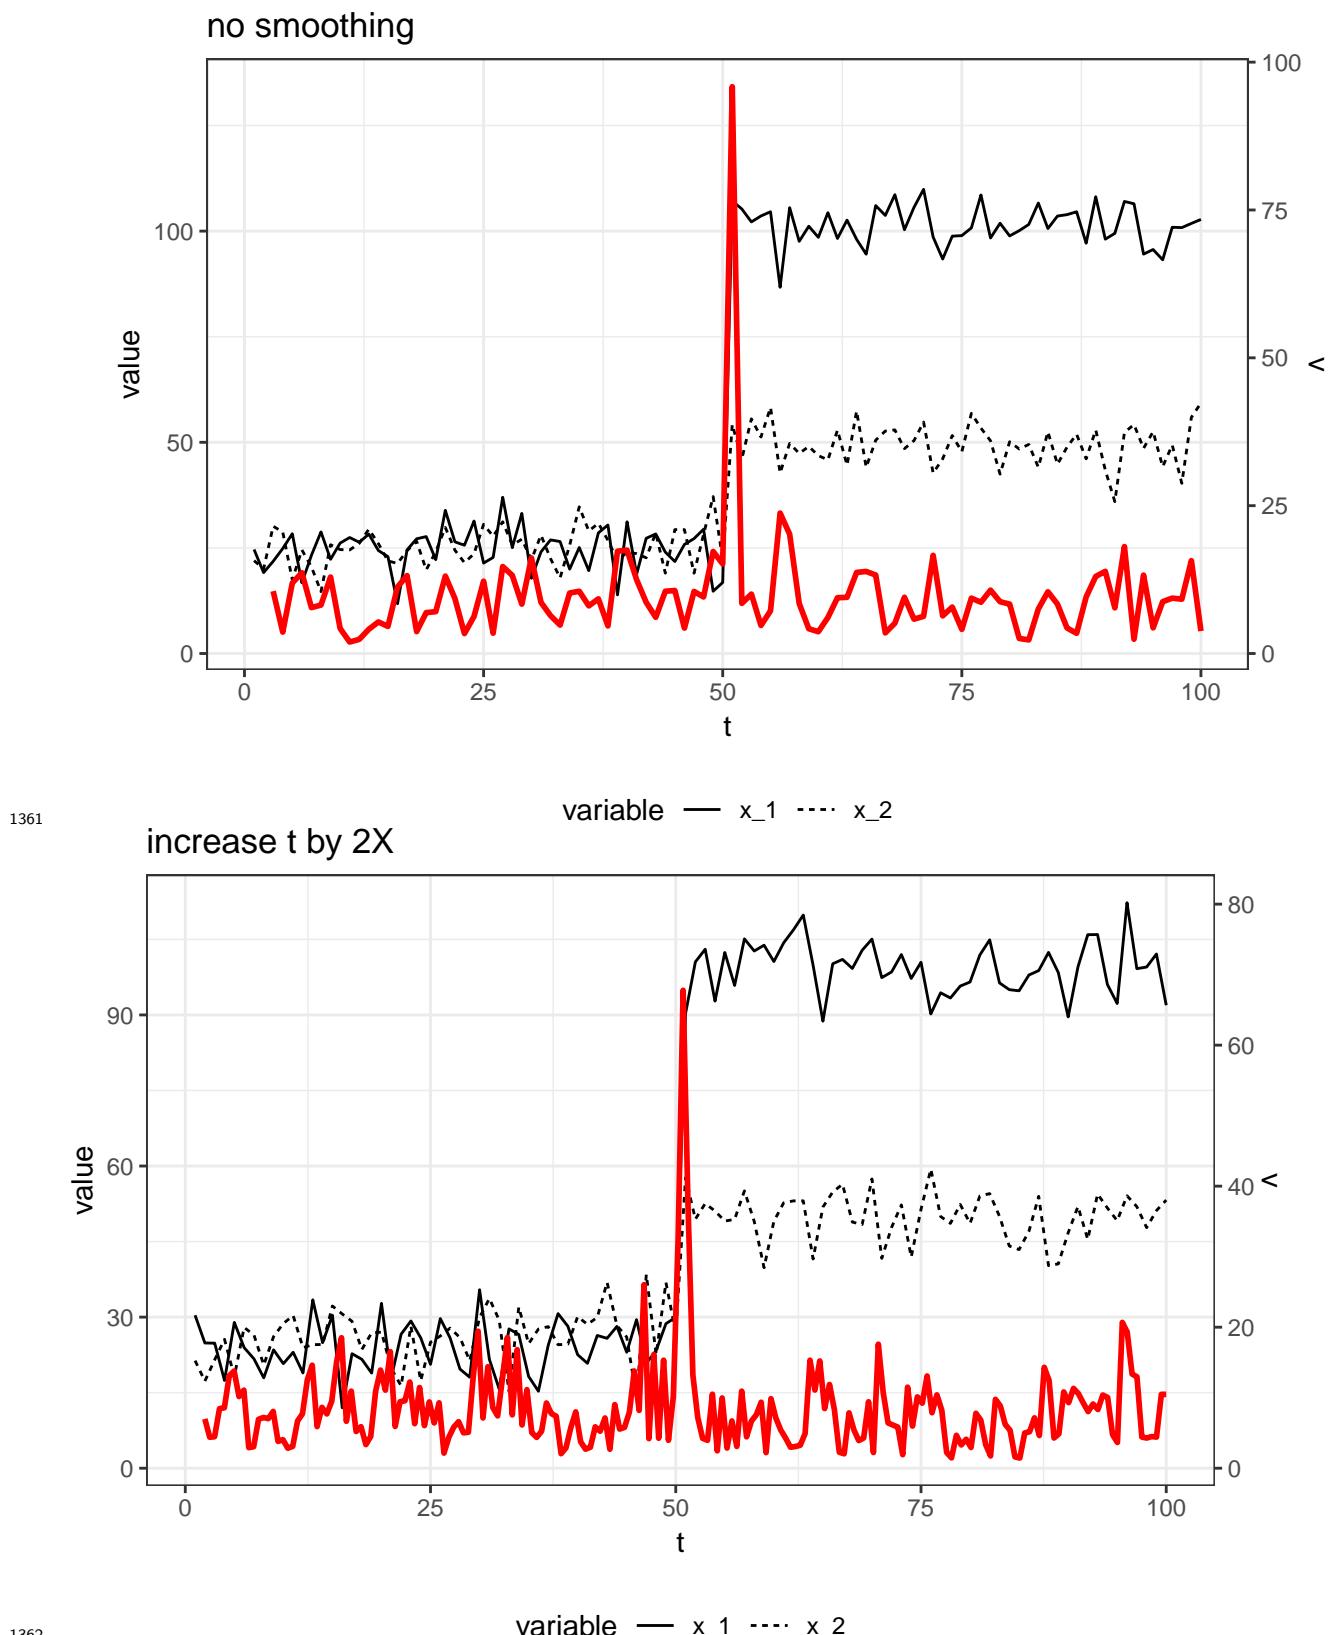

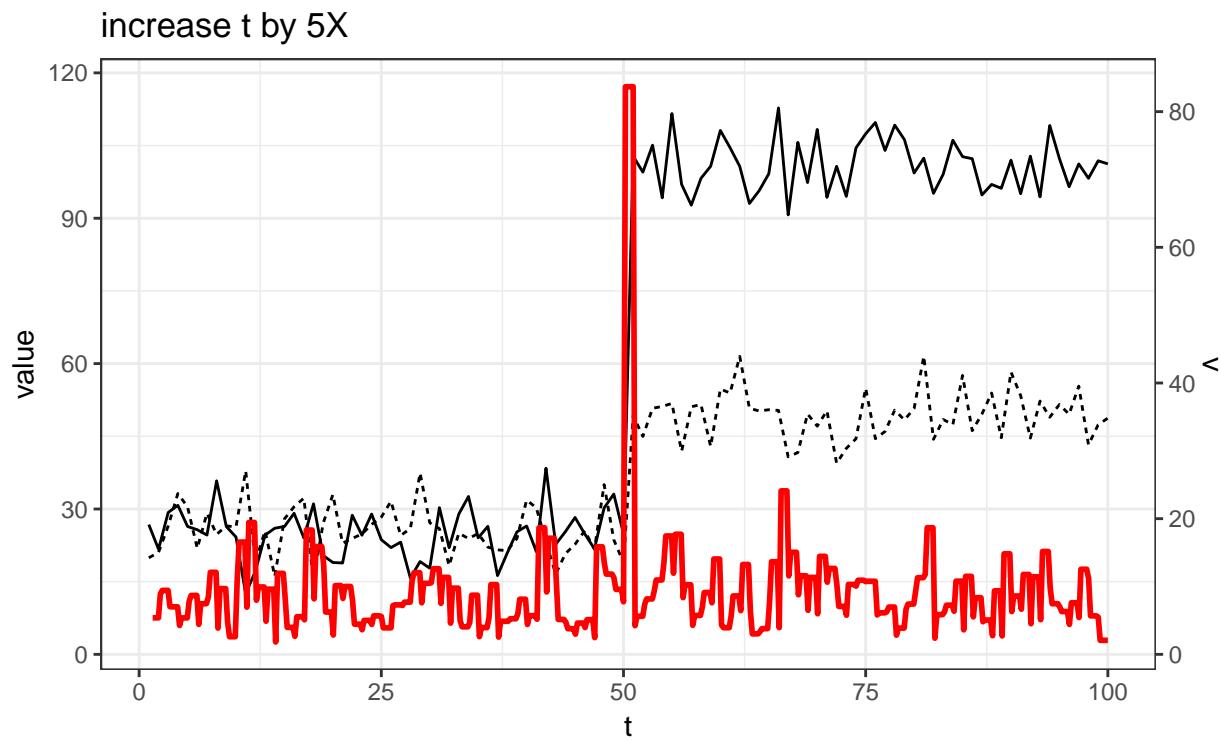

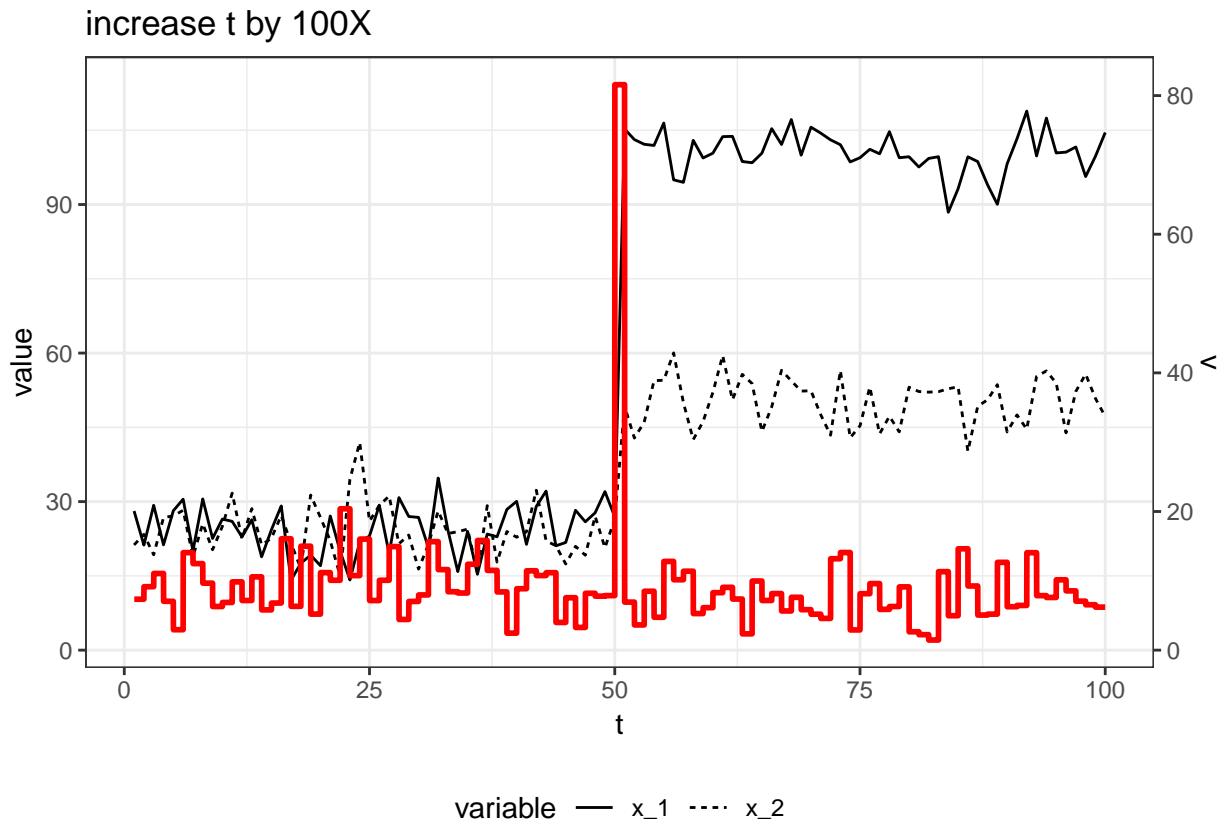

Figure 5.2: Average (± 2 SD) velocity (v) worsens as the variance of $\bar{x}_{2_{t=50(post)}}$ (post shift) increases. $\bar{x}_{1_{pre}} = 25$, $\bar{x}_{1_{post}} = 100$, $\bar{x}_{2_{pre}} = 25$, $\bar{x}_{2_{post}} = 50$, $\sigma_{1_{pre}} = 5$, $\sigma_{2_{pre,post}} = 5$

1353 **Smoothing the data prior to calculating v**

1354 To ameliorate the influence of noise (e.g. Fig. ??) on the regime shift signal in v , I
1355 used linear approximation techniques in attempt to smooth the velocity (derivatives).
1356 I used the function *stats::approx* to interpolate values of x_1 and x_2 to regularly-spaced
1357 time points in the set $t = \{1 : 100\}$, and then calculated v as described in the steps
1358 above (Eqs. (5.1):(5.6)). Increasing the number of points (t) at which the original
1359 state variables were smoothed did not influence the amount of noise surrounding the
1360 signal of the regime shift (at $t = 50$) in system velocity, v (Fig. ??).

1365 **5.2.4 Performance of velocity using empirical data: paleodi-**
1366 **atom community example**

1368 To gather baseline information on the use of velocity in empirical systems data,
1369 I calculated velocity for the paleodiatom system described in Chapter 6 (see also
1370 Appendix ???. Briefly, the paleodiatom community comprises 109 time series over
1371 a period of approximately 6936 years (Fig. 5.3). As elaborated in Spanbauer et
1372 al. (2014), the paleodiatom community is suggested to have undergone regime shifts
1373 at multiple points. These abrupt changes are apparent when exploring the relative
1374 abundances over time, as there are extreme levels of species turnover at multiple
1375 points in the data (Fig. 5.3). Using Fisher Information and climatological records,
1376 Spanbauer et al. (2014) suggest that regime shifts in this system at approximately
1377 1,300 years before present (where present is equal to year 1950). Spanbauer et al.

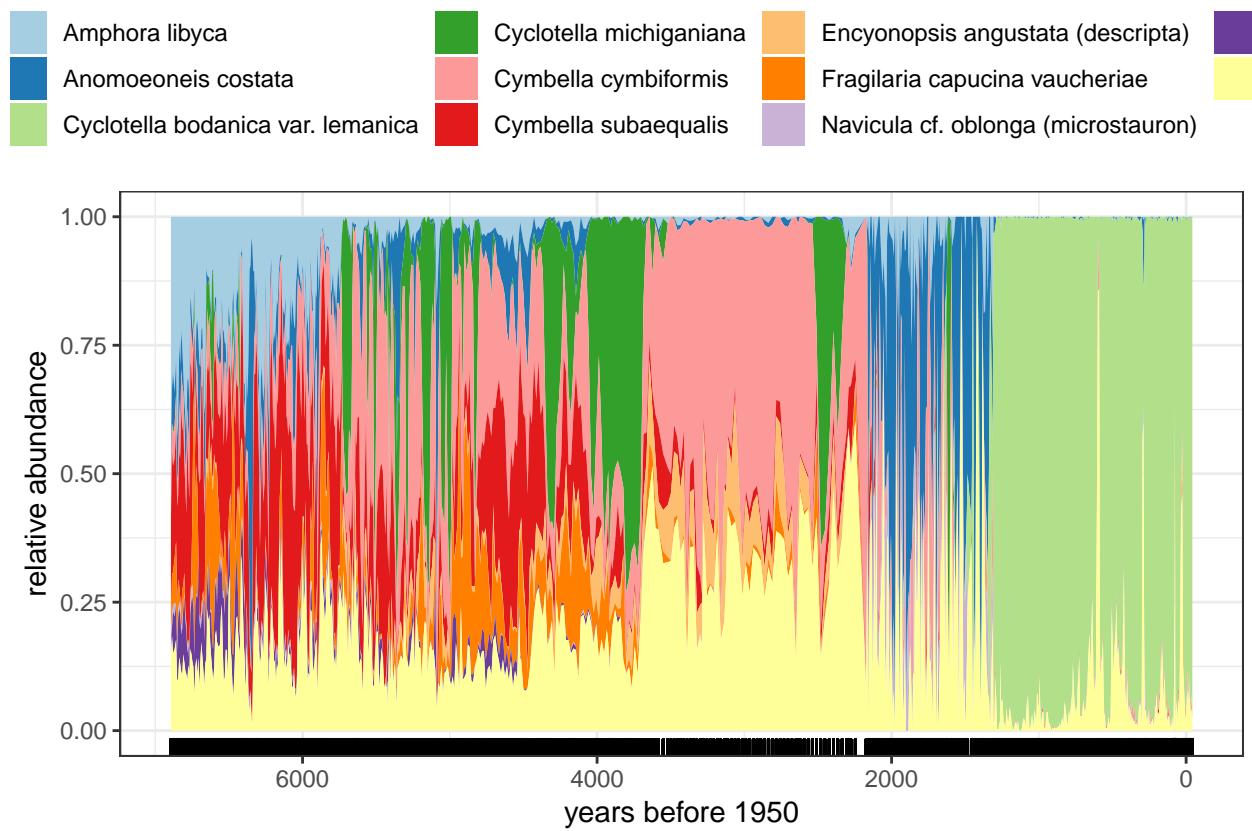

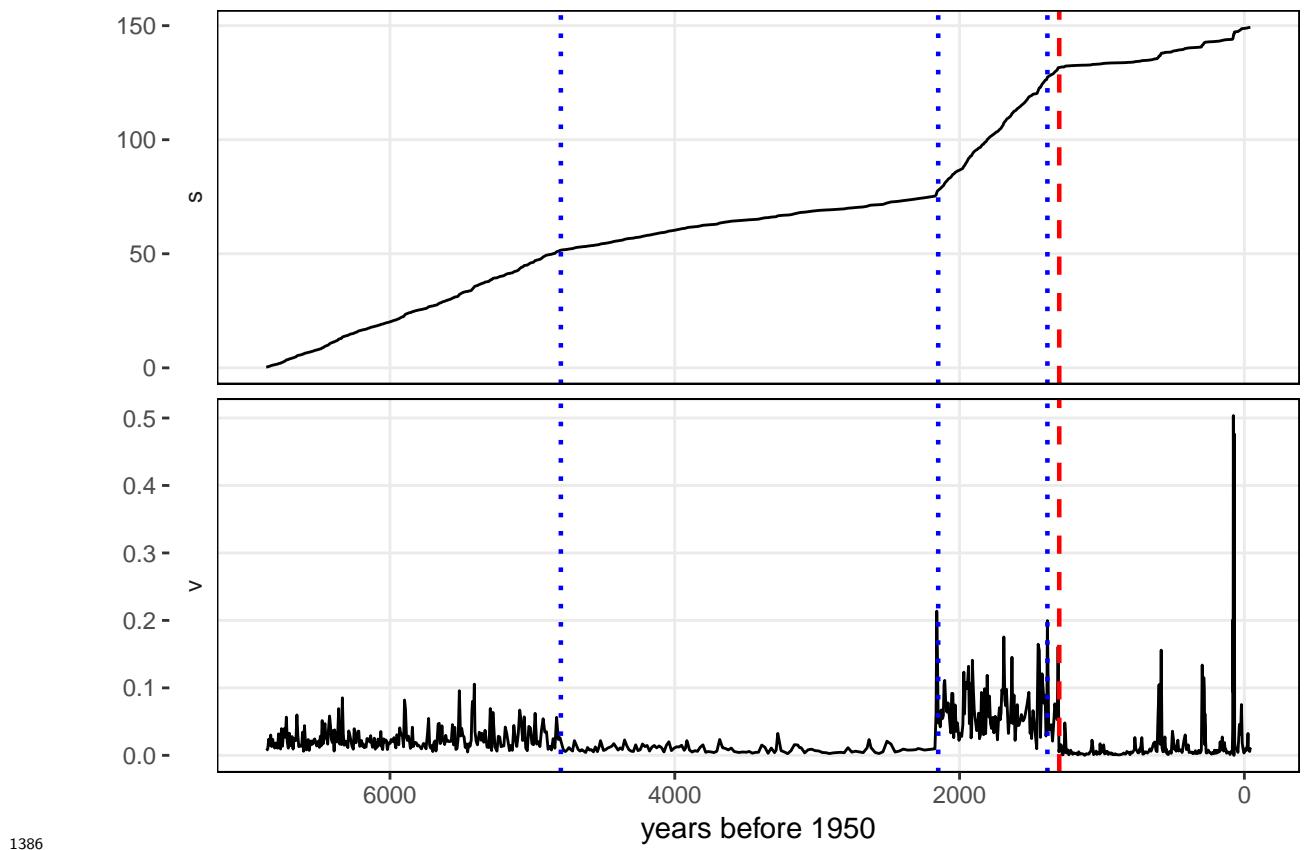

Figure 5.3: Relative abundances of the most common diatom species in the time series. Few species dominate the data over the entire time series, and turnover is apparent at multiple observations.

1378 (2014) used different regime detection metrics coupled with regional climatological
1379 events to identify regime shifts in the system, suggest that a regime shift occurred
1380 at $\sim 1,300$ years before present. Using the methods outlined above, I calculated the
1381 distance travelled (s) and velocity (v ; Fig. 5.5). The results of v and s (??) on the
1382 relative abundance data correspond with both the large shifts in species dynamics (see
1383 Fig 5.3, and also with the regime shift identified by Spanbauer et al. (2014). However,
1384 two primary results can be made from the metrics v and s that are not obvious nor
1385 identified numerically in the results of Spanbauer et al. (2014) ():

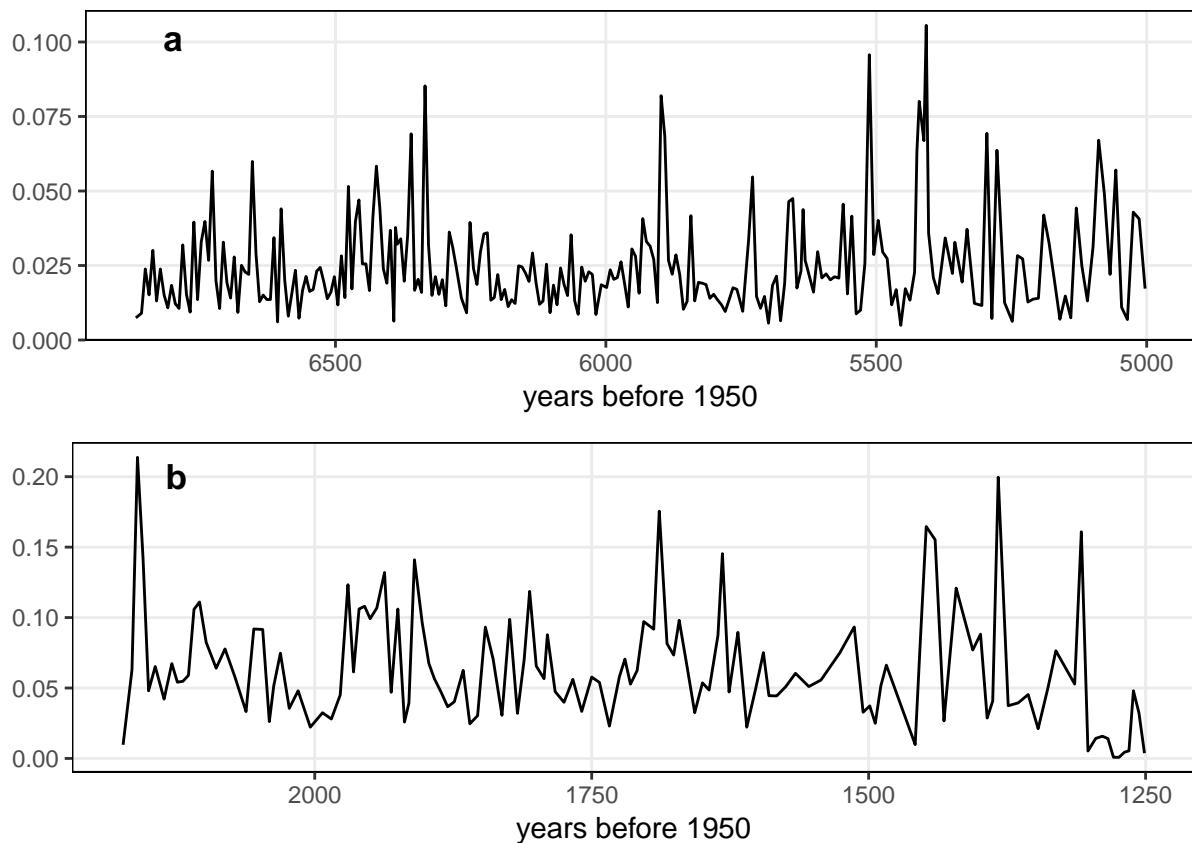

1386

1387 1. Two additional large shifts occurred at approximately 2,500, 4,800 and years before

1388 1950

1389 1. The periods before the first and after the second large shifts appear oscillatory

1390 (Fig. ??).

1391

1392 To determine whether removing the noise in the data, I interpolated the each time
 1393 series using function `stats::approx` to 700 time points. Next, I calculated the
 1394 distance travelled of the entire system, s . Finally, I obtained the derivative of s by
 1395 using a regularized differentiation (using function `tvdiff::TVRegDiffR`; parameters
 1396 were $iter = 2000$, $scale = \text{small}$, $ep = 1 \times 10^{-6}$, and $\alpha = 100$)¹.. This method of
 1397 regularized differentiation is an ideal approach to smoothing s because it assumes the
 1398 data are non-smooth, unlike other popular smoothing techniques e.g., Generalized
 1399 Additive Models. The smoothed velocity (5.5) provides a similar but smoother
 1400 picture of the velocity of the system trajectory. Comparing the smoothed (5.5) to
 1401 the non-smoothed velocity (??) yields similar inference regarding the location of the
 1402 regime shifts at 2,200 and 1,300 years before present, but more clearly identifies the
 1403 inter-regime dynamics (e.g., between 7,000 and 4,800 years before present).

¹*We created the R-wrapper `tvdiff` as a Python wrapper for the `tvdiff` MatLab package (???)

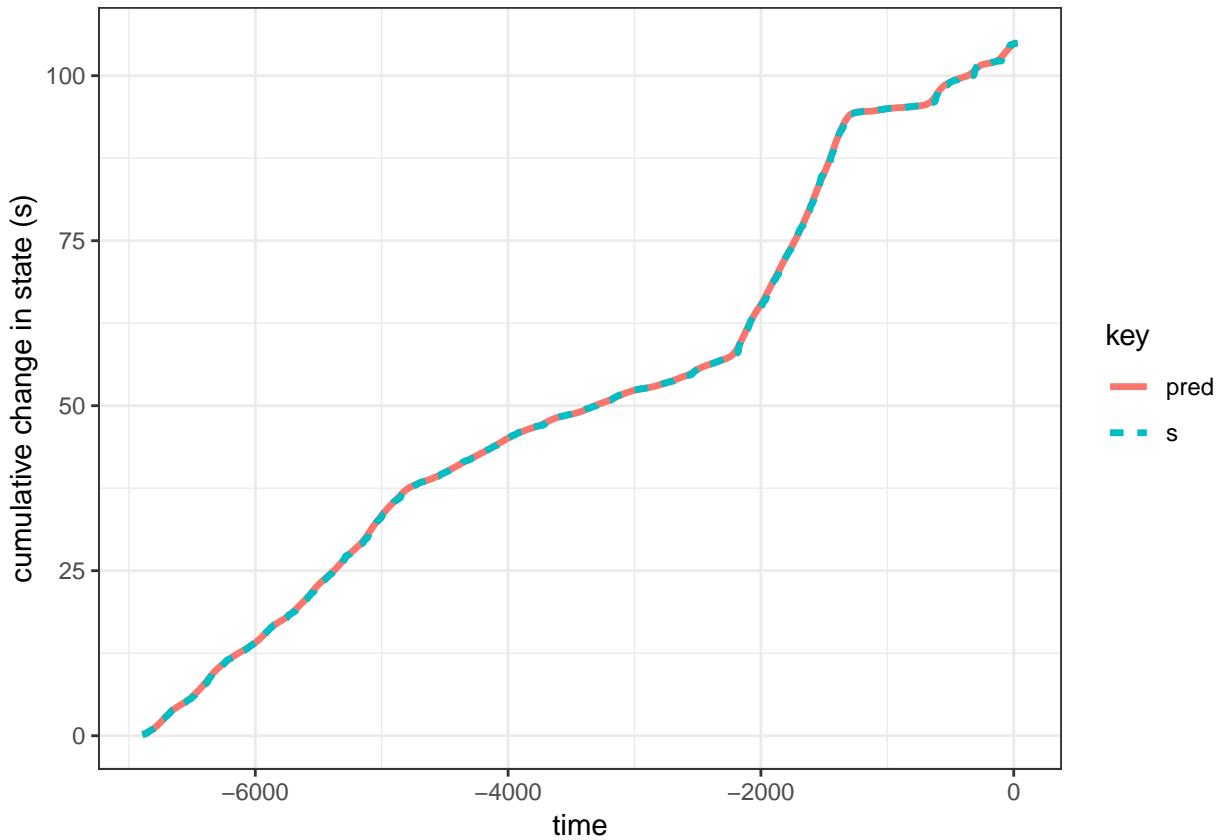

Figure 5.4: The regularized differentiation of s was best fit using $\alpha = 100$. Higher overlap of s and pred indicates a good fit of the regularized differentiated metric to the non-smoothed metric, s .

1404 5.3 Discussion

1405 In this chapter, I described the steps for calculating a novel regime detection metric,
1406 system velocity (v). First described in Fath et al. (2003), v is used as a single step
1407 for calculating a more complicated regime detection metric, Fisher Information (see
1408 also Chapter 3). System velocity is arguably simple to calculate, as shown in this
1409 chapter, captures the total change in system variables under a variety of mean and
1410 variance conditions. The metric does not, however, perform well as variance increases
1411 (Fig. ??), and smoothing the original data does not reduce the noise surrounding
1412 this metric when variance is moderate (Fig. ??).

1413 Variance is a commonly-used indicator of ecological regime shifts (Brock & Car-

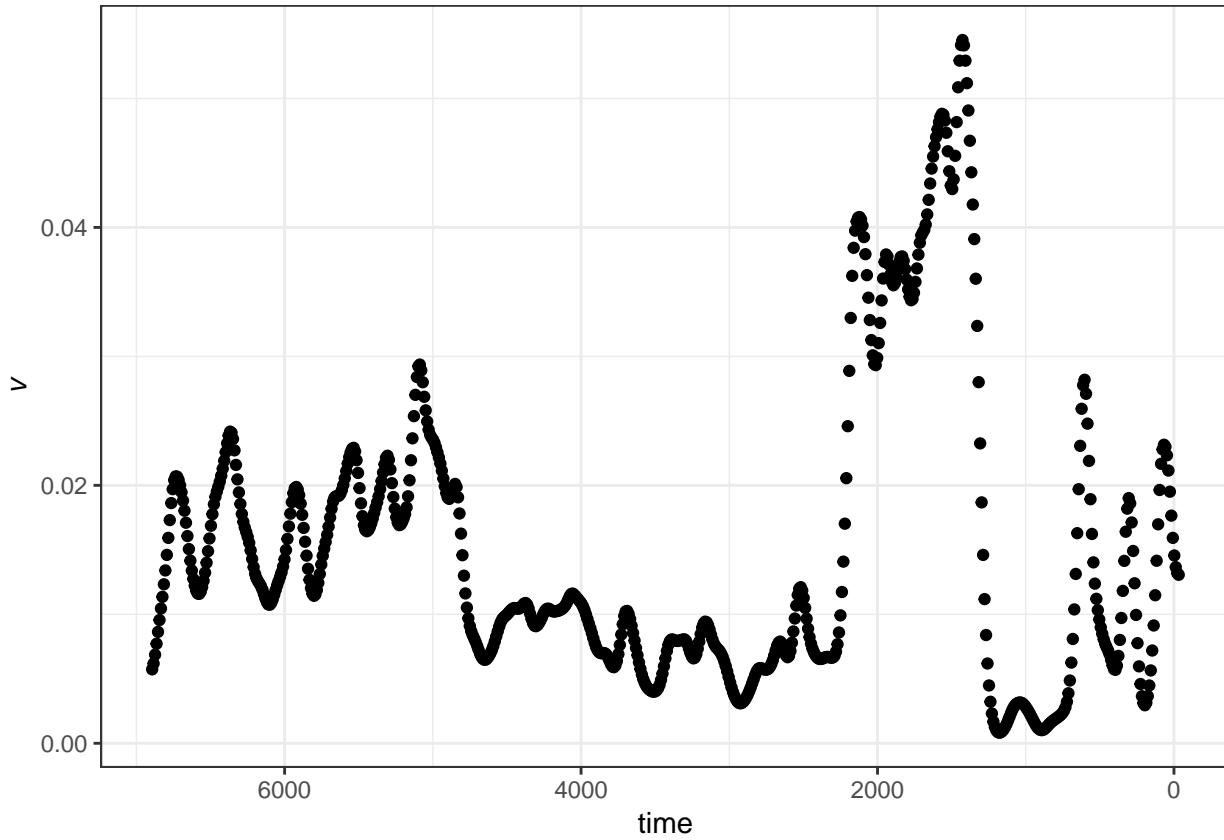

Figure 5.5: Need a caption here!!!

¹⁴¹⁴ penter (2006)), however, fails to perform when the number of variables is \gg a few.
¹⁴¹⁵ System velocity, v , may be useful in situations where the number of state variables is
¹⁴¹⁶ much greater than a few, and appears especially useful when the magnitude of change
¹⁴¹⁷ in one or more state variables is high (Fig. ??). For example, this method will likely
¹⁴¹⁸ identify signals of regime shifts where the shift is defined as high species turnover
¹⁴¹⁹ within a community.

¹⁴²⁰ I tested the efficacy of this metric as an indicator of abrupt change in a two-variable
¹⁴²¹ system. Although a useful first step, this metric should be considered in a multi-
¹⁴²² species context, and particularly in community-level empirical data which is difficult
¹⁴²³ to simulate. I demonstrate a compelling case study in materials associated with my R
¹⁴²⁴ Package, **regimeDetectionMeasures**, and in Appendix ?? in which multiple species
¹⁴²⁵ turnover events are apparent in a paleodiatom community time series. In this case

study, the ‘distance travelled’, s (Eq. (5.4)), clearly exhibits shifts at points where expert opinion and species turnover (in species dominance) agree that a large change occurred. Further, velocity, v (see *dsdt* in the package materials) indicates a large shift at only the most predominant shift in the time series, perhaps due to the metric’s sensitivity to variance (Fig. ??).

Further work is required to determine the utility of system velocity as a regime detection metric, however, this chapter demonstrates that the metric may indicate clear shifts in variable means. For multispecies data you will typically need to reduce dimensionality before you can proceed with analyses, for example using some sort of ordination. In addition to examining high-dimensional and noisy data, a study of the performance of v under conditions where few variables exhibit large changes while many variables are relatively constant may also prove useful. Additionally, this metric may be a useful tool for reducing the dimensionality of high dimensional data. Although the metric loses much information, as opposed to some dimension reduction techniques, e.g. Principal Components Analysis PCA, the metric is simple to calculate (even by hand), is computationally inexpensive, and is intuitive, unlike many clustering algorithms (e.g., Non-metric Multidimensional Scaling NMDS). Like system velocity, methods of the latter variety (e.g. NMDS) require post-hoc statistical analyses to confirm the location of clusters (or abrupt change, regime shifts), while methods of the former variety (e.g. PCA) retain loadings but do not necessarily identify the locations of abrupt shifts.

5.4 Supplementary Materials

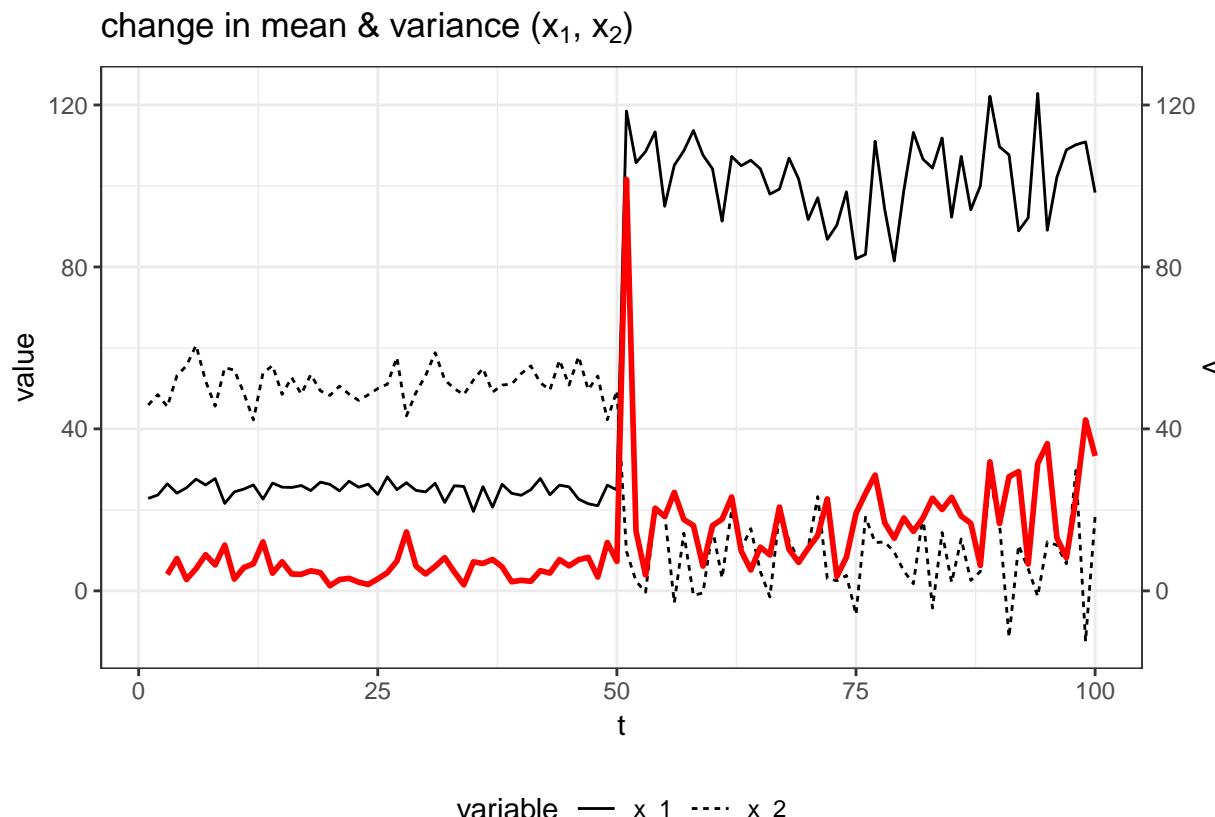

Figure 5.6: System change (s) and velocity (v) of the model system over the time period. Change in means ($\bar{x}_{1_{pre}} = 25$, $\bar{x}_{1_{post}} = 100$, $\bar{x}_{2_{pre}} = 50$, $\bar{x}_{2_{post}} = 10$) and an increase in variance ($\sigma_{1_{pre}} = 2$, $\sigma_{1_{post}} = 10$, $\sigma_{2_{pre}} = 5$, $\sigma_{2_{post}} = 10$).

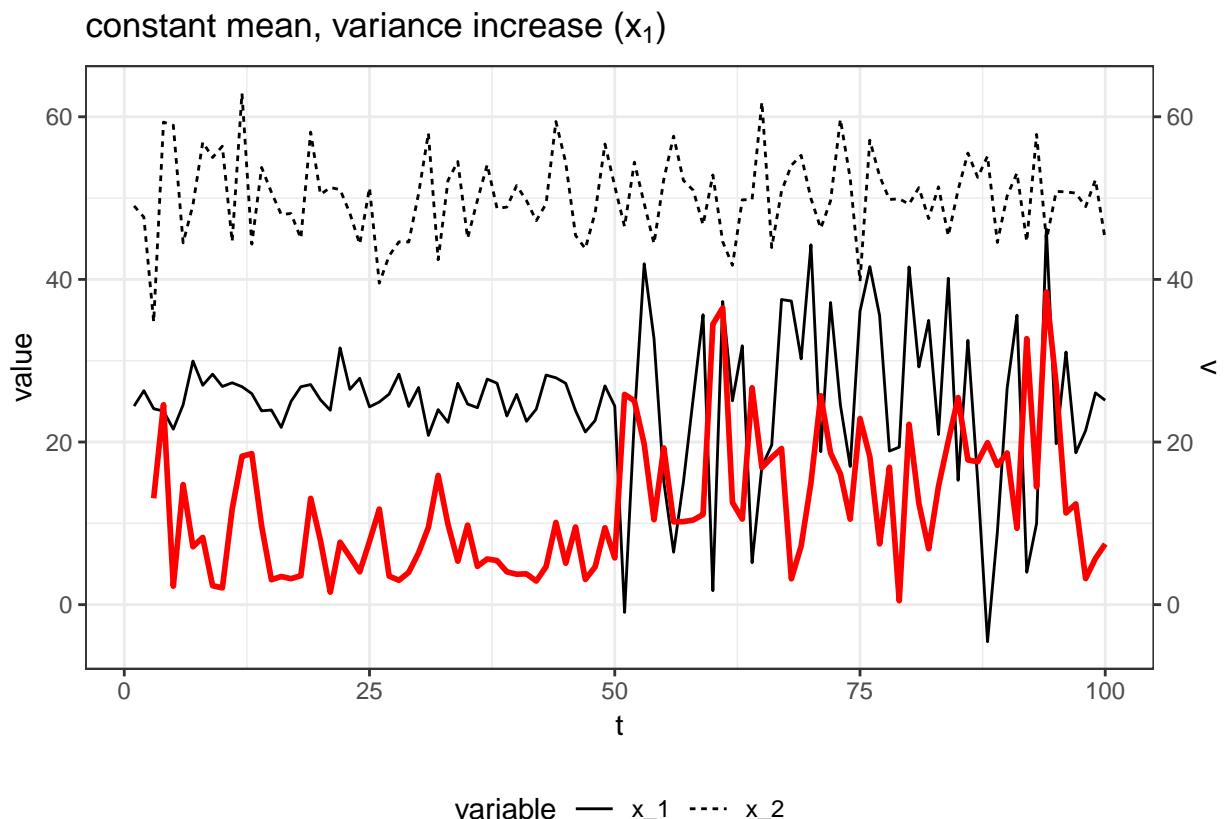

Figure 5.7: System change (s) and velocity (v) of the model system over the time period. Constant means ($\bar{x}_1 = 25$, $\bar{x}_2 = 50$) and sharp change in variance for one state variable $\sigma_{1_{pre}} = 2$, $\sigma_{1_{post}} = 12$, $\sigma_{2_{pre,post}} = 5$

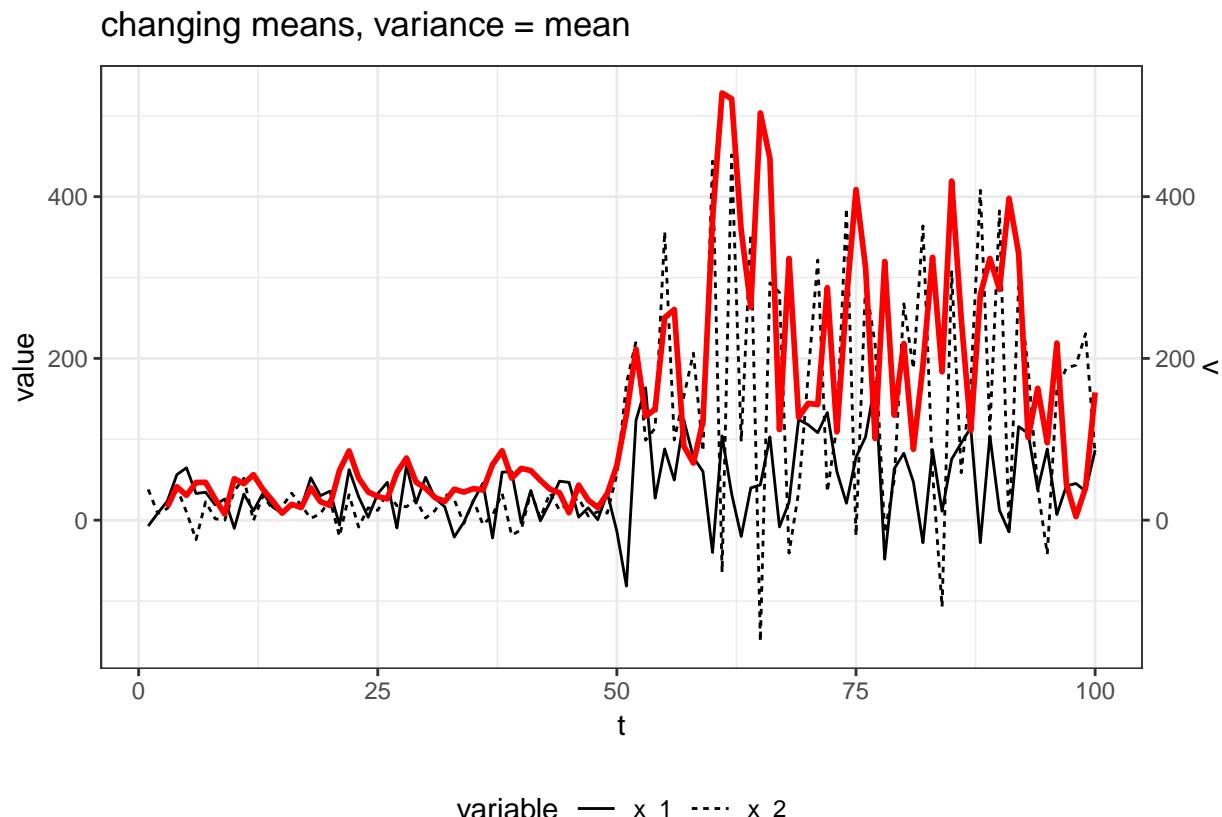

Figure 5.8: System change (s) and velocity (v) of the model system over the time period. Variance equal to mean ($\bar{x}_i = \sigma_i$), where means ($\bar{x}_{1_{pre}} = 25$, $\bar{x}_{1_{post}} = 50$, $\bar{x}_{2_{pre}} = 15$, $\bar{x}_{2_{post}} = 150$).

1448 **Chapter 6**

1449 **Robustness of Multivariate Regime**

1450 **Detection Measures to Varying**

1451 **Data Quality and Quantity**

1452 **6.1 Introduction**

1453 Ecological systems have many unpredictable and variably interacting components
1454 (Jørgensen et al. 2011). Methods for analyzing these complex systems, e.g. Dynamic
1455 Bayesian Networks, network models, and food webs are designed to handle these
1456 complexities, yet require data- and knowledge-intensive models. Although ecological
1457 data collection and data management techniques are improving (La Sorte et al. 2018),
1458 the aforementioned approaches to modeling and understanding complex system are
1459 often infeasible in ecosystem research and management (Clements et al. 2015).

1460 A growing concern with anthropogenic impacts on the environment has increased
1461 the demand for mathematical and statistical techniques that capture these dynamics.
1462 These often undesirable changes in the structure or functioning of ecological systems
1463 are often referred to as *regime shifts*, *regime changes*, *state change*, *abrupt change*, etc.

1464 (Andersen et al. 2009) . A yet-unattained goal of ecological research and management is
1465 to reach a point where these methods can predict impending regime shifts in real-time
1466 and with high confidence. Ideally, ecological regime shift detection methods (hereafter,
1467 regime detection measures) would require little knowledge of the intrinsic drivers of
1468 the system, and the users of the method would not be required to know if and where
1469 a regime shift occurred in the data.

1470 Despite the suite of regime detection measures in the environmental and ecological
1471 research literatures, they are not used in ecological management. We can describe
1472 the current state of regime detection measures as being either system specific (i.e.,
1473 the method is not widely applicable or generalizable across systems) or not. Methods
1474 of the latter type are convenient in that they can be applied across various system
1475 and data types, but the results of these analyses require some degree of subjective
1476 interpretation (Clements and Ozgul 2018; c.f. Batt et al. 2013). Efforts to develop
1477 and/or improve regime detection measures that can handle these biases will aid the
1478 advance of regime detection measures research and application.

1479 Current efforts to improve regime detection measures may be stunted by the lack of
1480 application beyond simple and/or theoretical (toy) systems data. Like most statistical
1481 and mathematical approaches, the evolution of many regime detection measures begins
1482 with application to theoretical data, followed by application to empirical data. Current
1483 applications of regime detection measures to empirical, ecological data are largely
1484 limited to data describing populations (e.g., Anderson and Piatt 1999, Alheit et
1485 al. 2005, deYoung et al. 2008), climatic, marine (e.g., Lipizer et al. n.d., Nicholls
1486 2011), and Paleolithic regime shifts (Spanbauer et al. 2014, Yang et al. 2017, Kong et
1487 al. 2017), with few applications to terrestrial data (*c.f.* Bahlai et al. 2015; Sundstrom
1488 et al., 2017). Although testing the performance and inference boundaries of theoretical
1489 and simple systems is important, they are of little use to ecosystem managers if they
1490 are not proven to be easily and reliably applicable to their system. Additionally,

1491 regime detection measures should be capable of handling empirical ecological data are
1492 often sparse and noisy.

1493 Ecological systems data is not only expensive to capture, but are often difficult
1494 to perfectly capture due to the large process and observation errors. The variability
1495 resulting from imperfect observation influences data quality and quantity, sometimes
1496 limiting the potential numerical tools used to identify trends and changes in the
1497 system in question (Thrush et al. 2009). Some methods, new and old, are proposed
1498 in the literature as regime detection measures which are capable of handling data
1499 limitation and quality issues inherent in ecological data and require few subjective
1500 decisions for choosing state variables and interpreting results. For example, variable
1501 reduction techniques, e.g. principal components analysis (Rodionov 2005, Andersen
1502 et al. 2009, Reid et al. 2016) and clustering algorithms (Weijerman et al. 2005,
1503 Weissmann and Shnerb 2016), an index of variance (Brock and Carpenter 2006) and
1504 Fisher Information (Cabezas and Fath 2002, Fath and Cabezas 2004, Karunanithi et
1505 al. 2008) were introduced as methods which collapse the system into a single indicator
1506 of ecological regime shifts. Although these methods have been tested on empirical
1507 ecological systems data, their robustness to empirical data quality and quantity have
1508 yet to be examined.

1509 In this Chapter I examine the influence of observation and process errors on the
1510 inference obtained from select multivariable regime detection measures. There are two
1511 major objectives:

- 1512 1. Identify the effects of data quality on regime detection measure inference.
- 1513 2. Identify the effects of data quantity on regime detection measure inference.
- 1514 3. Explore the relative performance of velocity (described in Chapter 5) to the
1515 abovementioned methods under multiple scenarios.

1516 This Chapter provides baseline relative performance estimates of select, multivariable

regime detection measures under various scenarios of data quality and quantity. The results from this Chapter inform the practical ecologist of the potential limitations to consider when applying these regime detection measures to their data, and has potential to inform the data collection process. Additionally, the software accompanying this Chapter allows the end user to implement these methods on this diatom system, a toy system, or their own data.

6.2 Data and Methodology

6.2.1 Study system and data

I used paleodiatom time series from a freshwater system in North America (Foy Lake, present day Montana) that apparently underwent a rapid shift in algal community dynamics at multiple periods in time. This datum comprises a single soil core sample, from which the relative abundances of 109 diatom species were identified at 768 observations (time points) over \approx 7,000 years (Figure 6.1. Althouh the soil core was sampled at regular distances, the soil accumulation process is not necessarily linear over time, resulting in irregularly-sampled observations (i.e., time elapsed between sampling points differs varies; see Figure 6.2). This datum was published in Spanbauer et al. (2014) and can be downloaded at the publisher's website.

6.2.2 Regime detection measures

Fewer model-free regime detection metrics exist than do model-based metrics (Chapter 2) and of these, only a few are suggested for handling multivariable data. Here, I examine the regime detection metrics that are model-free and can handle multivariable data: velocity (Chapter 5), the Variance Index (Brock & Carpenter, 2006) and Fisher Information. These methods and the primary sources are described below.

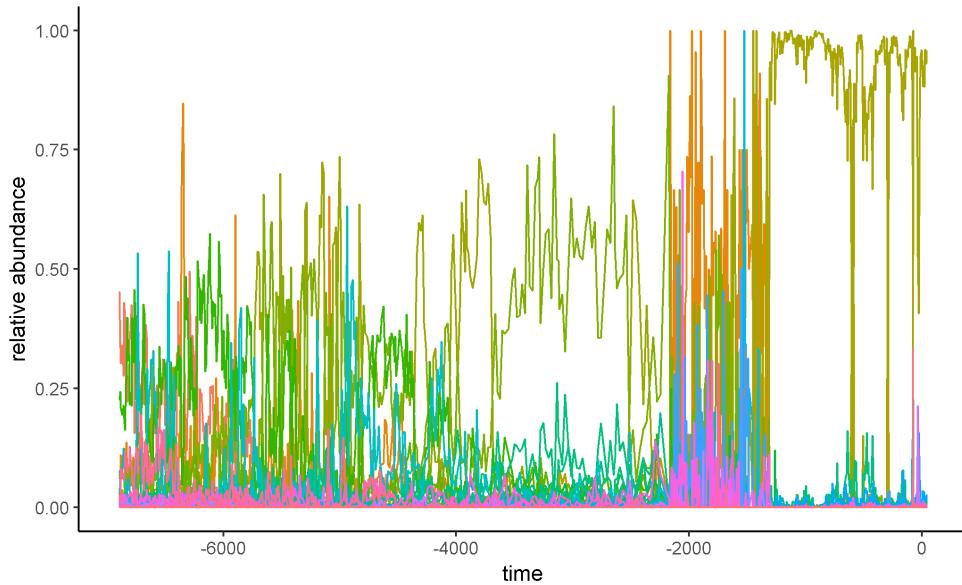

Figure 6.1: Relative abundances of the diatom species in Foy Lake over the time period.

1540 Velocity (v)

1541 In Chapter 5, I describe a new method, **velocity**, v , as a potential dimension reduction
1542 and regime detection method. First introduced in by Fath et al. (2003) as one of
1543 multiple steps in calculating their variant of Fisher Information, velocity calculates
1544 the cumulative sum of the square root of the sum of the squared change in all state
1545 variables over a period of time (Eq. (6.1)). Steps for calculating this metric are
1546 described in detail in Chapters 3 and 5.

$$\Delta s_i = \sqrt{\sum_{j=1}^n (x_{i,j} - x_{i-1,j})^2} s_k = \sum_{i=2}^k \Delta s_i 2 \leq k \leq nv = \frac{\Delta s}{\Delta t} \quad (6.1)$$

1547

1548 Variance Index

1549 The Variance Index was introduced by Brock & Carpenter (2006), and is simply
1550 defined as the maximum eigenvalue of the covariance matrix of the system over some

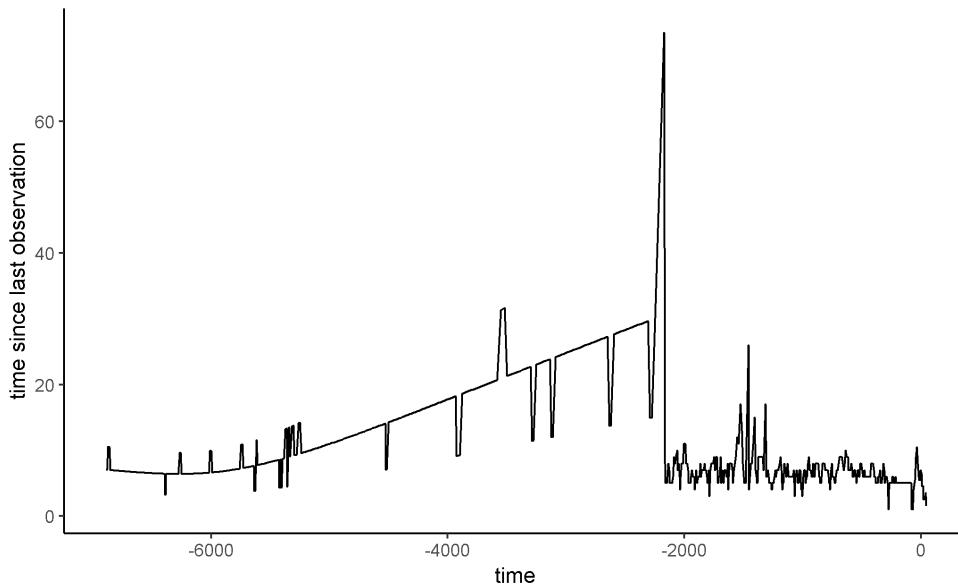

Figure 6.2: The amount of time elapsed between observations.

1551 period (window) of time. The Variance Index (also called Variance Indicator) was
 1552 originally applied to a modelled system (Brock & Carpenter, 2006), and has since been
 1553 applied to empirical data (Spanbauer et al., 2014; Sundstrom et al., 2017). Although
 1554 rising variance has been useful in many real systems (van Nes and Scheffer 2003,
 1555 Brock et al. 2006, Carpenter and Brock 2006), the Variance Index, which is intended
 1556 for multivariate data, appears most useful when the system exhibits a discontinuous
 1557 regime shift (Brock & Carpenter, 2006).

1558 Fisher Information

1559 Fisher Information (I) is essentially calculated as the area under the curve of the
 1560 acceleration to the fourth degree (s''^4) divided by the squared velocity (s'^2 ; also
 1561 referred to as v in Chapter 5) of the distance travelled by the system, s over some
 1562 period of time (T), and is given in Eq. (6.2):

$$I = \frac{1}{T} \int_0^T dt \left[\frac{s''^2}{s'^4} \right]^2 \quad (6.2)$$

1563 I describe this method in detail in Chapter 3.

1564 **Using moving window analysis to calculate Fisher Information and Vari-**
1565 **ance Index**

1566 Unlike *velocity*, the Variance Index and Fisher Information are calculated using moving
1567 window analysis. That is, over the entire time series, T^* , these metrics are calculated
1568 within multiple windows of time, T . In this approach, all state variables, x_i , are used
1569 to inform the calculations (of Variance Index and Fisher Information) over a time
1570 interval, T , where T is the length in [time] units of the time interval and satisfies the
1571 following conditions: $T < T^*$ and $2 \leq T < (T^* - 1)$. If $T = T^* - 1$, then only a single
1572 value of the metrics will be calculated for entire time series, which does not allow for
1573 any estimate of change.

1574 When using these metrics in the context of identifying abrupt changes in ecological
1575 systems data across T^* , it is ideal the value of T meets the following conditions:
1576 $3 < T \ll T^* - 1$. The length of a time window dictates the number of calculations
1577 one can obtain over T^* , such that the number of potential metric calulations increases
1578 as $\frac{T}{T^*}$ decreases. Previous applications of moving window analyses to calculate Fisher
1579 Information found that at least eight observations (time points) should be used.

1580 An additional parameter is required when conducting moving window analyses:
1581 the amount of time points by which the window advances. In order to maximize
1582 the data, I force the window to advance at a rate of one time unit. However, it is
1583 important to note that because these data are not sampled annually and the because
1584 the window always advances by a single time unit, the number of observations included
1585 in each calculation will not be the same. If fewer than 5 observations are in a window,
1586 I did not calculate metrics, advancing the window forward. I assigned the calcuated
1587 values of Fisher Information and Variance Index within each moving window to the
1588 **end** (the last time unit) of the moving window. I temporal analyses, assigning the

1589 value to any other point in time (e.g., the beginning or the middle) muddles the
1590 interpretation of the metric over T^* . Also note that this method has the potential to
1591 result in calculating a metric for all integers between $0.20T^*$ and T^* .

1592 **6.2.3 Resampling Techniques for Simulating Data Quality
1593 and Quantity Issues**

1594 Using a bootstrap approach I calculated the regime detection measures over varying
1595 degrees of scenarios to simulate data quality and data quantity issues that are common
1596 to ecological data analysis. The scenarios are categorized as *observations* and *species*.
1597 The observations scenario simulates a loss of temporal observations (decreasing the
1598 number of times the system was observed), and the species scenario simulates a loss of
1599 information about the system by removing a larger proportion of the species. The loss
1600 of temporal observations and the loss of species were examined at three proportions:
1601 $\mathbf{P} = [0.25, 0.50, 0.75, 1.00]$, where \mathbf{P} is the proportion of species and time points
1602 retained for analysis. For example, when $\mathbf{P} = 0.25$, a random selection of 25% of the
1603 species are retained for analysis in the species scenario. I bootstrapped the datum
1604 over 10,000 iterations for each scenario and \mathbf{P} combination. Note that because when
1605 $\mathbf{P} = 1.00$, all data are retained. Therefore, no resampling was conducted at this level
1606 because only a single metric (e.g. Velocity) value is possible.

1607 Interpretation of the regime detection measures used in this analysis are currently
1608 limited to visual inspection. Therefore, I limit inference in this study largely to the
1609 impact of data loss on the variability with a regime detection measure (i.e. how robust
1610 is the measure to data loss).

1611 6.3 Results

1612 In many cases the standard deviation of FI far exceeded the mean value of FI. I
1613 calculated the coefficient of variation, $\frac{\sigma}{\mu}$, for each ?????!!!!???? as the proportion of data
1614 (and observations) used decreased. For example, when when we retained

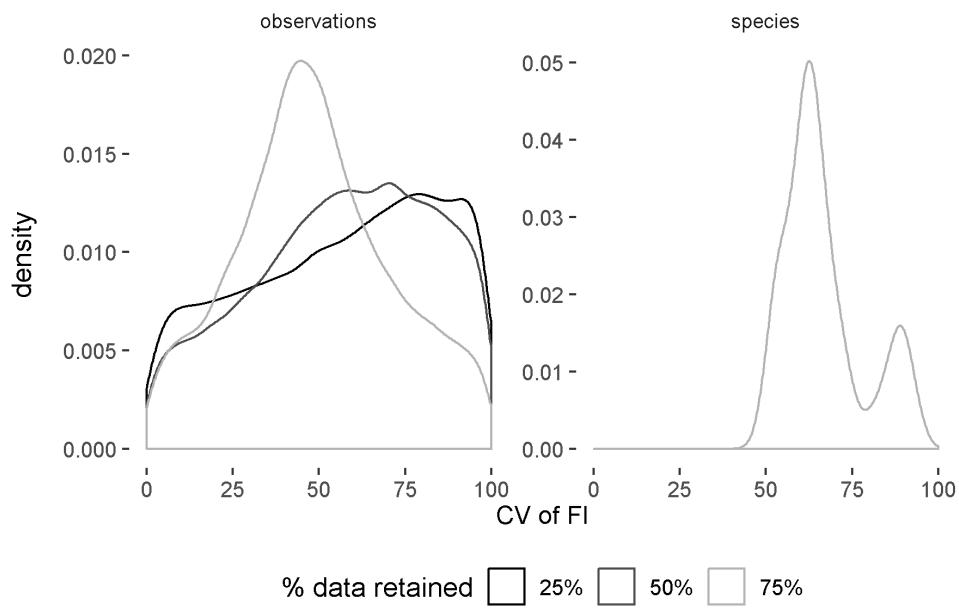

1615 **6.3.1 Velocity of the distance travelled produces similar re-**
1616 **sults with information loss**

1617 Ad lorem ipsum blahblahlhba

1618 **6.3.2 Variance Index produces**

1619 **6.3.3 Fisher Information is highly sensitive to information**
1620 **loss**

1621 When we bootstrap 25% of the species, the ratio of mean Fisher Information to
1622 standard deviation of Fisher Information (over 10,000 iterations) is always < 1 ,
1623 suggesting Fisher Information does not produce fidel results when information is lost
1624 about the system.

1625 \begin{figure}
1626 \caption{Density plot of the coefficient of variation (CV) as a percentage (%) of the
1627 Fisher Information bootstrapped samples (10,000 iterations). Densities based on all
1628 values of CV, but values >100% are not printed.} \end{figure}

1629 6.4 Discussion

1630 6.5 Acknowledgements

1631 This study was conceptualized at the International Institute for Applied Systems
1632 Analysis (IIASA) as part of the Young Scholars Summer Program in 2018. I thank my
1633 IIASA program supervisors, Drs. Brian Fath and Elena Rovenskaya, for advisement
1634 during this period.

₁₆₄₃ **Conclusions**

$$\begin{aligned} Data &= Information \\ &= Signal \quad (8.1) \\ &= Process + Noise \end{aligned}$$

₁₆₄₄ Climate change is expected to induce an increase in both the intensity and frequency
₁₆₄₅ of rapid ecological change or disturbance, impacting social systems, potentially to
₁₆₄₆ the detriment of human communities most vulnerable. Identifying and forecasting
₁₆₄₇ these changes is critical for community and ecological planning, management, and
₁₆₄₈ disaster mitigation. Because ecological and social systems are tightly coupled, it is
₁₆₄₉ commonplace to use ecological indicators to identify change and potential changes that
₁₆₅₀ may impact these systems. Many papers introducing or discussing regime detection
₁₆₅₁ measures suggest the ecologist uses multiple lines of evidence, ranging from historical
₁₆₅₂ observations to ecological modelling results, for identifying an ecological regime shift
₁₆₅₃ (Lindgren et al., 2012). Although valid, comparing results of multiple methods or lines
₁₆₅₄ of evidence within a single system has yielded inconsistent results, and inconsistent
₁₆₅₅ results can result in either improper conclusions, or in what I am calling **method**
₁₆₅₆ **mining**. That is, a dataset is analyzed using until a sufficient number of methods
₁₆₅₇ yield affirmative results.

1658 8.1 Method mining regime detection methods

1659 Many regime detection measures have yet to be properly and statistically (or numerically) scrutinized. However, it should be noted that, in part due to both (i) the
1660 popularity and (ii) the sheer number of ‘new’ methods a handful of authors¹.
1661

1662 Managing systems using quantitative methods that yield different results may yield
1663 improper management techniques and objectives. ->

1664 Ecological indicators (a.k.a. indices, metrics) have been suggested as ‘early-warning
1665 indicators’ of ecological regime shifts or abrupt change (Chapters 1 and 2). Ecological
1666 indicators (or indices) are methods of measurement which are designed to provide
1667 inference about one or more unobserved or latent processes, are inherently biased.
1668 Regardless of the state of the theory supporting *regime shifts* in ecology, ecological
1669 indicators and the methods for calculating them should be heavily scrutinized prior to
1670 being used in an ecological management or policy-making setting. Rather, new methods
1671 (indices, metrics, etc.) are being introduced into the literature at a rate exceeding
1672 that at which they are scrutinized (Chapter 2). This dissertation demonstrates that,
1673 while potentially useful, regime detection metrics are inconsistent, not generalizable,
1674 and are currently not validated using probabilities or other statistical measurements
1675 of certainty.

1676 8.2 Ecological data are noisy

1677 Regime detection metrics appear more reliable when the signal-to-noise ratio is high
1678 (Ch. 2, Ch. 5, ???). Ecological systems are noisy, and the observational data we are
1679 collecting at large scales (e.g., the North American Breeding Bird survey), is noisy.
1680 Using methods incapable of identifying meaningful signals in noisy data appears futile,

¹S.R. Carpenter is one example of an author who has relative infamy in the field and has, as primary author or otherwise, introduced a relatively large number of new methods (e.g., rising variance, the variance index, Fourier transform, online dynamic linear modelling, TVARSS, to name a few)

₁₆₈₁ yet, methods for doing so are increasingly introduced in the scientific literature (Ch.
₁₆₈₂ 2).

₁₆₈₃ 8.3 Data collection and munging biases and limits ₁₆₈₄ findings

₁₆₈₅ Regime detection measures and other ecological indicators can signal (see (8.1))
₁₆₈₆ various changes in the data, however, understanding what processes are embedded
₁₆₈₇ in the signals (i.e., removing the noise) requires expert judgement. And because a
₁₆₈₈ consequence of data collection and data analysis limits the extent to which we can
₁₆₈₉ identify and infer processes and change within an ecological system, **I suggest the**
₁₆₉₀ **practical ecologist scrutinizes her data prior to identifying and conducting**
₁₆₉₁ **analyses**, including those that are purely exploratory. By collecting and analysing
₁₆₉₂ data, the ecologist has defined the bounaries of the system *a priori*^{^+ (+} Beisner,
₁₆₉₃ Haydon, & Cuddington, 2003 states this eloquently as, “The number and choice of
₁₆₉₄ variables selected to characterize the community will be determined by what we wish
₁₆₉₅ to learn from the model”). The influence of state variable selection is ignored by some
₁₆₉₆ metrics (e.g. Fisher Information Eason, Garmestani, & Cabezas, 2014 and *v* Chapter
₁₆₉₇ 5), in that the resulting measure is composite and carries no information regarding
₁₆₉₈ the influence of state variables on the metric result.

₁₆₉₉ The actual limitations to the system should be, theoretically, known as a result of
₁₇₀₀ bounding the system. Inference beyond this system is extrapolation, and should be
₁₇₀₁ treated as speculation, especially when not accompanied by a measure of uncertainty
₁₇₀₂ around one’s predictions.

1703 **8.4 Common Limitations of Regime Detection**

1704 **Measures**

1705 Limitations of the findings in this dissertation and of the regime detection methods
1706 used herein are largely influenced by the **data collection, data munging** processes.
1707 Although the below mentioned points may seem logical to many, these assumptions
1708 are overlooked by many composite indicators, including regime detection measures.
1709 1. Signals in the indicators are restricted to the ecological processes captured by the
1710 input data. Extrapolation occurs when processes manifest at scales different than the
1711 data collected. (resolution; Chapter ??)
1712 1. normalization and weighting techniques often impact results (whether ecological or
1713 numerical) (Appendices ?? and ??)
1714 1. data aggregation techniques often impact results (Chapter 6)
1715 1. some indices fail to generalize across systems or taxa (see Chapters 1 and ??)
